If the top switch, #6, is moved "OFF" and the mile rerun, the reading will be about .900 miles, a difference of .260 from the .640 mile reading above. If the #6 switch is moved "ON" and the #5 switch is moved "OFF" and the mile rerun, the new reading will be .770 miles, a difference of .130 from the .640 mile reading above and half the difference of .260 caused by the #6 switch.

From the foregoing discussion, it can be seen that moving a switch rearward, ("ON"), subtracts from the reading, moving a switch forward, ("OFF"), adds to the reading. Furthermore the switches have the following approximate values over a one mile distance:

Switch Number	Value
6	.256
5	.128
4	.064
3	.032
2	.016
1	.008

20273

Over a one quarter mile distance the switches will give one fourth of the above changes as follows:

Switch Number	Value
6	.064
5	.032
4	.016
3	.008
2	.004
1	.002

In order to add or subtract any given number to a distance reading, it will be necessary to move at least one switch and perhaps two or more. The next part of Section 6 on Initial Calibration is given as a guide to calibrating.

20274

6A. Initial Calibration

The initial calibration procedure must be carried out when the computer is first installed and at any subsequent time when a routine calibration check shows the calibration to be out of tolerance (as set forth in the calibration check procedure). The initial calibration is carried out as follows:

a. Open the calibration switch cover located on the left hand side of the main computer near the front panel. Inside will be six slide switches numbered one through six from bottom to top, respectively. Initially, set the switches as follows:

Switch Number	Position *
6	OFF
5	ON
4	ON
3	OFF
2	OFF
1	OFF

b. With the calibration switches set in the above positions, run a measured quarter-mile in the following manner: With the computer erased and ready

---

*Note: "OFF" is the forward position of the switch
"ON" is the rearward position of the switch

20275

to accept a set of readings, stop well ahead of the beginning quarter-mile mark. Start the car and bring it up to approximately 25 MPH. Turn on the distance switch when abreast of the beginning quarter mile mark. Drive approximately 25 MPH speed to the end mark and stop. Turn OFF the distance switch. With the readout selector switch in the distance (MILES) position, sequence the time switch ON then OFF so that the distance readout will appear. Record the distance reading.

c. From the Calibration Table (See Figure III.17), re-position the calibration switches as shown in the column corresponding to the distance reading obtained above.

d. The computer is now ready for a calibration check.

NOTE: To use a measured half-mile or measured mile for calibration, divide the obtained distance reading by two for the half-mile reading or by four for the mile reading, and use the resulting number with the calibration table.

Safety Rules for the Metal Shear

1. Check setup of machine.
2. Do not attempt to cut metal heavier than capacity of machine.
3. Cut narrow strips of metal crosswise only.
4. Stand directly in front of machine.
5. Feed metal from the front (operator's position)
6. Keep your fingers away from the pressure bar and the blade.
7. Keep the foot that is not being used on the treadle back out of the way.
8. Do not catch small pieces--let them drop.
9. Use care in handling trimmings--they may be sharp.

7. Calibration Check

Before each tour of duty, a routine calibration check must be performed. This is done as follows: With the computer erased and ready to accept a set of readings, stop well ahead of the beginning measured quarter-mile mark (a measured half-mile or mile may also be used). Bring the car up to approximately 25 MPH. Turn ON the distance switch, when abreast of the beginning quarter-mile mark. Drive at approximately 25 MPH speed to the end mark and turn OFF the distance switch. Using an accurate watch, enter 15 seconds into the time register (enter 30 seconds for a measured half-mile or 60 seconds for a measured mile).

To be within tolerance the distance reading must agree with the measured distance within 1/4 of 1%. (i.e. .250 ± .001, .500 ± .002, or 1.000 ± .004) It has been found that an experienced operator can enter time into the computer usually within two-tenths of a second. If the time is not within two-tenths of a second (i.e. 15.0 ± 0.2, 30.0 ± 0.2, or 60.0 ± 0.2), turn ON the distance lock, erase, and re-enter the required time.

(Note: The time generation technique used in the TDS Computer is highly stable and accurate. Any small difference between the watch reading and the computer time reading is due solely to the operator's inability to obtain absolute synchronization in starting and stopping the time devices.)

If the distance reading is not within the required

20279

1/4 of 1%, re-calibrate the distance as outlined in Section 6 of this chapter. A small time difference due to the reason given above (usually less than ± 0.2 seconds) is normal for an experienced operator. A large time difference (which is very unlikely) indicates a failure in the computer's clock circuit and, in this event, the device must be taken in for repair.

With the time and distance properly entered and in tolerance, the following charts showing the resulting miles-per-hour reading for given time and distance are used to verify that the computer is indeed computing properly.

Distance = 0.249

Time	MPH
14.8	60.1
14.9	59.7

COMPUTATION CHECK -

ONE MILE CALIBRATION

8. Error Analysis

Due to the digital nature of the TDS Computer, the time and distance readings can be in error by plus-or-minus one count. The TDS Computer gives the traffic violator the benefit of doubt by automatically subtracting the worst case error. The miles-per-hour reading of the TDS Computer is always within ± 1 MPH of the slowest possible speed corresponding to the time and distance readings. Some examples are:

a. Distance Reading = 0.100 miles

Time Reading = 3.2 seconds

MPH Reading = 109.0 MPH

MPH corresponding to time and distance readings is

$$\text{MPH} = \frac{0.100 \text{ miles}}{3.2 \text{ seconds}} \times \frac{3600 \text{ seconds}}{\text{hour}} = 112.5 \text{ MPH}$$

Worst case error yields

$$\text{MPH} = \frac{0.099 \text{ miles}}{3.3 \text{ seconds}} \times \frac{3600 \text{ seconds}}{\text{hour}} = 108.0 \text{ MPH}$$

b. Distance Reading = 1.000 miles

Time Reading = 60.0 seconds

MPH Reading = 59.9 MPH

MPH corresponding to time and distance readings is

$$\text{MPH} = \frac{1.000 \text{ miles}}{60.0 \text{ seconds}} \times \frac{3600 \text{ seconds}}{\text{hour}} = 60.0 \text{ MPH}$$

Worst case error yields

$$\text{MPH} = \frac{0.999 \text{ miles}}{60.1 \text{ seconds}} \times \frac{3600 \text{ seconds}}{\text{hour}} = 59.8 \text{ MPH}$$

20283

c. Distance Reading = 0.250 miles

Time Reading = 15.0 seconds

MPH Reading = 59.6 MPH

MPH corresponding to time and distance readings is

$$\text{MPH} = \frac{0.250 \text{ miles}}{15.0 \text{ seconds}} \times \frac{3600 \text{ seconds}}{\text{hour}} = 60.0 \text{ MPH}$$

Worst case error yields

$$\text{MPH} = \frac{0.249 \text{ miles}}{15.1 \text{ seconds}} \times \frac{3600 \text{ seconds}}{\text{hour}} = 59.4 \text{ MPH}$$

d. Distance Reading = 0.100 miles

Time Reading = 6.0 seconds

MPH Reading = 59.0 MPH

MPH corresponding to time and distance readings is

$$\text{MPH} = \frac{0.100 \text{ miles}}{6.0 \text{ seconds}} \times \frac{3600 \text{ seconds}}{\text{hour}} = 60.0 \text{ MPH}$$

Worst case error yields

$$\text{MPH} = \frac{0.099 \text{ miles}}{6.1 \text{ seconds}} \times \frac{3600 \text{ seconds}}{\text{hour}} = 58.4 \text{ MPH}$$

Figure III.18 shows the worst case error and readout compensation versus speed for various clocking distances.

Since the device automatically compensates for its internal error, the only error to be considered by the enforcement officer is the error in judging coincidence between the violator's vehicle and the reference point. The Error Factor Chart of Figure III.19 gives the error in MPH versus the error in distance (i.e. error in coincidence), as a function of measured speed and total clocking distance. This is calculated from the formula:

$$\text{MPH ERROR} = \frac{\text{DISTANCE ERROR}}{\text{CLOCKING DISTANCE}} \times \text{MEASURED MPH}$$

Figure III.18

Safety Rules for the Forge

1. Do not light forge without special permission.

2. Keep flammable materials away from forge area.

3. Read manufacturer's instructions or follow this procedure to light the forge:
   - A. Wear appropriate eye protection.
   - B. Run air for about two minutes.
   - C. Turn off air.
   - D. Place lighted piece of paper in the forge.
   - E. Create draft by turning on air slowly.
   - F. Turn on gas slowly.
   - G. Adjust valves to confine all flame within the forge.

4. Practice handling work with appropriate pliers or tongs <u>before</u> heating it.

5. Be careful in handling long or heavy pieces.

6. Be careful when carrying hot metal. Warn others by calling out, "Hot metal!"

7. Consider all metal around the furnace and the furnace itself as being hot.

8. If it is necessary to leave hot work, mark it "HOT" with chalk or soapstone or use a special sign.

9. Inspect hammer faces and handles before using.

10. Never strike hammer on hammer or hammer on anvil. Hardened faces may fracture and send chips of metal flying.

11. Protect your face when quenching metal.

12. To turn off furnace, shut off Gas <u>first</u>, then the air.

13. Quench hot tongs before returning to their storage place.

CHAPTER IV

TDS COMPUTER TRIAL GUIDE

The following "Trial Guide" is made a part of this manual with the hope that it may prove to be of assistance to the prosecuting attorney in the preparation of speeding cases where the TDS Computer was used to determine the speed of the violator. It is recognized that some of the questions may be objectionable and that the questions are not necessarily presented in the most logical order. However, review of these questions and answers before such a case is presented may assist in the formulation of more suitable questions. In speeding cases the problem of proof ultimately resolves itself into two general categories: (1) the reliability and accuracy of the method or device used, and (2) the skill and credibility of the officer. Keep in mind that the fact situations are given for illustration purposes only. The specific facts of any case may make some of the examples inapplicable and may require the formulation of additional questions.

1. Direct Examination of the TDS Operator

Q. What is your name?

A. John Robertson.

Q. What is your occupation?

A. I am a trooper on the State Highway Patrol.

Q. How long nave you been a member of the State Highway Patrol?

A. Nine years.

20287

Q. On July 3, 1968, were you so employed?

A. Yes, sir.

Q. What sort of duty were you engaged in on that date?

A. I was on routine patrol.

Q. What area were you working on that date?

A. I was working U.S. 24 in Forrest County from the airport to the Westville City Limits.

Q. On that date, was your patrol car equipped with any devices designed and used to measure the speed of your vehicle or other vehicles?

A. Yes, sir. My car was equipped with a speedometer and a TDS Computer.

Q. Have you had any training in the use of either of these devices?

A. Yes, sir. I have.

Q. Please describe this training.

A. I attended a course of instruction at the Police Academy. This course included lectures on the operation of the TDS Computer and a 15-day practice period. I then underwent a series of certification tests.

Q. Did you successfully complete this training and the certification tests?

A. Yes, sir. I did.

Q. Do you have a certificate or other evidence of proficiency in the use of the TDS Computer?

A. Yes, sir, I have. After successfully completing the training and passing the qualification test, I received a Certificate of Proficiency as a TDS Computer Operator from the Director of the Police Academy.

Q. Please explain to the jury what a TDS Computer is.

A. A TDS Computer is an electronic computer which automatically computes speed in miles per hour when quantities of time and distance are fed into it.

Q. How does a TDS Computer operate?

A. The TDS Computer is equipped with two toggle switches, one of which controls the time measuring protion of the computer and one which controls the distance measuring mechanism. These switches are manually turned on and off by the operator of the computer. The time switch is used to measure the elapsed time of a violating vehicle between two reference points on the highway. The distance switch is used to measure the distance between the same two points.

Q. Is the principle of the TDS Computer based on any scientific facts or principles?

A. Yes. It is based on the mathematical formula for determining speed; Speed = Distance divided by Time, or $S = \frac{D}{T}$.

Q. How is the TDS Computer used to measure the speed of another automobile?

A. The suspected violator is timed between two reference points on the highway. This is done by the operator of the computer. He turns on the time switch when some part of the violating vehicle is directly abreast of one reference point, and he turns the time switch off when some part of the violating vehicle is directly abreast of the second reference point. The operator measures the distance by passing the same reference points and turning the distance switch on and off when the enforcement vehicle is in the same relative position to the reference points. The computer then has both the necessary quantities, time and distance. The speed is indicated on a digital readout. The violating vehicle is always timed between two points and the distance is always measured by the enforcement vehicle. There is no sequence in which time and distance are measured. The TDS Computer can measure either time or distance first, or it can measure both at the same time.

Q. What sort of reference points may be used by the computer operator?

A. Nearly any object foreign to the surface of the highway may be used as a reference point, provided that it can be clearly seen by the TDS operator at the beginning and end of the clock. Examples are: Lines painted on the highway, cracks in the surface of the roadway, rocks, shadows, etc.

Q. How can the computer operator tell when the violating vehicle passes such a location point?

A. During the day shadows may be used to determine when the violating vehicle passes any given point. As the violating vehicle moves along the highway, it casts a shadow, either directly underneath the car or to one side or the other. The operator can watch this shadow as it approaches a preselected reference point. As the shadow strikes the reference point the time switch is turned on, and as the shadow strikes the second reference point the operator turns off the time switch. Stationary shadows cast upon the highway can also be used as reference points. The operator watches as the violating vehicle approaches the shadow and he turns the time switch on just as the violating vehicle passes into the shadow. He turns the time switch off when the car passes a second reference point. In either case, there is a noticeable change in light density when the shadow touches an object on the roadway or when the violating vehicle is touched by a shadow cast by a foreign object. Night use of the TDS Computer involves headlight reflections on stationary objects in much the same manner as daytime shadows are used.

Q. Is depth perception an important factor affecting the accuracy of measurement?

A. No, depth perception is not a factor because the shadow actually strikes the reference point, or the violating vehicle is touched by a shadow. When the violating vehicle's shadow touches an object on the roadway, it causes a definite change of light density. When the violating

287 OF 327

ED

056 238

MICROCOPY RESOLUTION TEST CHART

NATIONAL BUREAU OF STANDARDS-1963-A

vehicle is touched by a shadow cast by a fixed object, there is also a distinct change in light density. This is entirely different from the problem of attempting to align two objects some distance away which do not actually touch each other.

DEFINITION: DEPTH PERCEPTION - the ability to judge the distance of objects and the spatial relationship of objects at different distances.

Q. Is reaction time an important factor in using the TDS Computer?

A. No, reaction time is not an important factor because the computer operator is able to watch the shadow of the violating vehicle as it approaches the reference point, or the violating vehicle as it approaches a stationary shadow used as a reference point, and the operator can anticipate the time when the two will come in contact. This is very similar to a race track official's anticipating the time when a runner breaks the tape at the end of a race when the runner is being timed with a stopwatch. Therefore, true reaction time, which is a reaction to an unexpected event, is not involved.

DEFINITION: REACTION TIME - the time elapsed between perception and action.

DEFINITION: ANTICIPATION - the act of looking forward, i.e. Expectation.

Q. Does the TDS Computer display the top speed of a violating vehicle at any given instant?

20292

287

A. No, it computes the average speed; that is, the average speed for the amount of distance involved between the two reference points used. The average speed can never be greater than the top speed.

Q. What are the time and distance capacities of the TDS Computer?

A. The computer is designed to measure up to 15 minutes in time and up to 32 miles in distance.

Q. How is the time and distance information stored in the computer?

A. Both the time and distance are stored in separate electronic circuitries within the computer. These sections of the computer are commonly referred to as Data Storage Banks.

Q. Is the TDS Computer operator able to read out the amount of time elapsed and distance measured from the computer?

A. Yes, this information is stored in two separate memory units of the computer and the computer will display this information upon request. The distance is displayed in miles or portions thereof and time, in seconds or portions thereof.

Q. Can the TDS Computer be checked for accuracy?

A. Yes, it can be checked for accuracy very easily.

Q. How is this done?

A. One method is to feed a pre-measured distance into the computer. This is done by driving the computer-equipped

20293

enforcement vehicle over the measured distance, turning the distance switch on at one reference point and off at the other. After the known distance is fed into the computer, the operator can feed a known time into the computer by turning the time switch on and off simultaneously with a stopwatch. If he feeds 15 seconds into the computer, having already fed one-fourth mile into the computer, the result will be sixty miles per hour if the computer is properly calibrated.

Q. Why would the result be sixty miles per hour in that case?

A. At sixty miles per hour a car travels one mile in one minute. Therefore, if a car travels one-fourth mile in one-fourth minute it travels at sixty miles per hour.

Q. Can the TDS Computer be spot checked for accuracy by any other means?

A. Yes, the computer can be checked against the enforcement vehicle speedometer. The enforcement vehicle speedometers are calibrated and certified as correct. By very carefully maintaining a constant speed, the computer operator can turn on and off both the time and distance switches at the same time. If the speed of the enforcement vehicle has been held constant, the average speed reading of the computer should be the same as the speed indicated by the speedometer during the test.

Q. What can be done if the computer does not give the correct speed when a known time and a known distance are fed into it?

A. The computer can be calibrated to correct the error by correcting the distance imput into the computer.

Q. What factors would make calibration necessary?

A. Tire size is one factor. As a tire wears, it becomes smaller, thus requiring more revolutions of the wheel to measure a unit of linear distance. Tire wear is a very gradual change; however, it affects the distance measuring capability of the computer to a very insignificant degree. Another factor which makes calibration necessary is the changing of the computer from one enforcement vehicle to another, for the reason of differences in tire sizes.

Q. What is the policy of your department concerning the frequency of checking the accuracy of the TDS Computer?

A. The accuracy must be checked every day.

Q. How long have you had a TDS Computer in your enforcement vehicle?

A. I have had it in my car for six months.

Q. Have you checked the accuracy of the computer in your enforcement vehicle as required by Department policy?

A. Yes, sir. I have.

Q. How often have you found it necessary to calibrate and correct the computer?

A. In six months the accuracy of the computer in my enforcement vehicle has not changed significantly. (Be prepared to present your log of accuracy checks.)

Safety Rules for the Bench Furnace

1. Before attempting to light furnace, make sure gas valves are OFF.

2. If furnace does not have a pilot light, use this procedure to light:
   - A. Place a lighted piece of paper in the furnace
   - B. Slowly turn on the gas.
   - C. Adjust the flame so that all fire is contained within the furnace.

3. Place soldering copper on an prescribed rest when not in use.

4. Do not overheat coppers. Test for proper heat by touching the copper to a piece of solder.

5. Do not inhale fumes from soldering fluxes.

6. Use care in wiping excess solder from copper.

7. Wipe up spilled flux immediately.

8. When finished, turn off furnace and place "HOT" sign on it.

2005

Q. While on patrol on July 3, 1968, did you have occasion to observe an automobile being driven by the defendant?

A. Yes, sir.

Q. What kind of car was he driving?

A. He was driving a 1967 Ford.

Q. What, if anything, attracted your attention to the automobile that the defendant was driving?

A. The car appeared to be traveling at a speed greater than the normal flow of traffic.

Q. In what direction was the defendant going and in what direction were you going?

A. The defendant was going east and I was traveling west.

Q. Were you able to determine the speed of the defendant's car?

A. Yes, sir.

Q. What method or device did you use to make this determination?

A. I used the TDS Computer.

Q. How did you accomplish this?

A. As the defendant's car approached me, it passed over a patch in the roadway. The patch is asphalt and the pavement is concrete; therefore, a great contrast in color existed, supplying a very prominent reference point. The time switch was turned on at that point. When the defendant's car came abreast of the enforcement car, I turned off the time switch and started measuring distance. As the enforcement vehicle passed over the

asphalt patch, I turned off the distance switch. The computer then calculated the speed of the defendant's car.

Q. Do you know how much distance and time was fed into the computer, and if so, how much?

A. Yes, sir. The distance from the asphalt patch to the point where we passed was 0.5 mile and the elapsed time for the defendant to travel that distance was 20 seconds.

Q. How were these time and distance figures determined?

A. I queried the time and distance memory sections of the computer. These are the figures that were displayed on the digital readout screen.

Q. How were you able to remember the reference points and all of these figures?

A. Immediately after issuing the citation, I made notes, and I reviewed these notes prior to this court appearance.

Q. Is it true that the longer the clock, the more accurate it will be?

A. This is not necessarily true, although the longer the distance traveled , the more insignificant any error becomes in missing a reference point and, of course, since this method measures average speed, the longer the clock, the more benefit of the doubt is given the defendant should he deviate from his peak speed.

Q. How close do you think you can "call" a reference point when the violating vehicle is a tenth of a mile away?

A. Based on my training and experience with the TDS Computer and the tests which I have passed, I would estimate that I can come within four feet of the exact spot from a distance of one-tenth of a mile, under good conditions.

Q. Have you been furnished any material indicating what the error would be, if any, if you should misjudge a location point by four feet in a speed range of 90 miles per hour over, say, a half-mile clock?

A. Yes, sir. If I missed a reference point by four feet in a speed range of 90 miles per hour over a half-mile clock, the error would be 0.136 of a mile per hour.

Q. Now, if you missed a reference point by four feet each time you turned on and off the time and distance switches, there would be an error of four times this 0.136 of a mile per hour in this speed range, is this not true?

A. Yes, sir. If I missed it four feet each time I turned on and off the two switches, there would be an error of 0.544 miles per hour.

Q. What makes you think that you can call the reference points as closely as plus or minus four feet?

A. I feel that I can do this consistently because my training and testing for certification as a TDS Computer operator indicated that I am able to clock the speed of the violating vehicle twenty-five different and consecutive times with an

average error of less than one-half of one mile per hour.

Q. Based on your experience as a police officer, when you clock the speed of another car using the conventional speedometer method, how close do you think you can gauge speed?

A. I don't think anyone, including myself, can call a speedometer clock any closer than to the nearest whole mile per hour under the best possible conditions.

Q. Officer Robertson, are there any speed signs on U.S. 24 in Forrest County?

A. Yes, sir.

Q. Did you observe these signs on the date of the arrest?

A. Yes, sir.

Q. Are these official highway speed control signs?

A. Yes, they are.

Q. Are there any such signs located in the area in which this clock was made?

A. Yes.

Q. What is the speed indicated on the signs?

A. 60 miles per hour.

Q. Officer Robertson, you have passed a rigid training program and you are a Certified TDS Computer Operator. How can you assure the court that the clock you made on the defendant is accurate?

A. I was sure of my reference points and I was careful with my clock. Based on my experience and tests, I know that the speed indicated is correct within two miles per hour. Also, I would be glad to demonstrate my ability as a TDS Computer operator for the court, if the court deems this necessary.

Q. What did the TDS Computer indicate as the speed of the vehicle which the defendant was driving?

A. The TDS Computer indicated that he was traveling 90 miles per hour.

An Instructors Manual for a Three Week Course in Administration and Supervision of a Periodic Motor Vehicle Inspection.

Northwestern Univ., Evanston. Traffic Inst.
American Association of Motor Vehicle Administrators, Washington, D.C.
Automotive Safety Foundation, Washington, D.C.
Highway Users Federation for Safety and Mobility
MF AVAILABLE IN VT-ERIC SET.
PUB DATE - 70 416p.

DESCRIPTORS - *VOCATIONAL EDUCATION; *TEACHING GUIDES; *MANUALS; EDUCATIONAL OBJECTIVES; INSTRUCTIONAL MATERIALS; RESOURCE MATERIALS; ANNOTATED BIBLIOGRAPHIES; TEACHING TECHNIQUES; *MOTOR VEHICLES; *INSPECTION; SUPERVISORS

ABSTRACT - Prepared by the Traffic Institute at Northwestern University, this instructor's manual should be useful in a training program in Periodic Motor Vehicle Inspection (PMVI). As times change and PMVI programs develop, there will be need for updating the information in the manual. Therefore, instructors who use the manual should be constantly on the alert for supplementary material to improve this basic work. To adequately treat the 15 units in this source it is recommended that three weeks or 85 hours of instruction time be set aside. Covered by the 15 units are such topics as (1) Federal Programs, (2) Selection and Training of Supervisors, (3) Field Supervision and Enforcement, (4) Records and Information, (5) Planning--A Function of Management, and (6) Budgeting--A Function of Management. This loose-leaf notebook is arranged in outline format and provides (1) objectives for each unit, (2) suggested teaching time, (3) suggested teaching techniques, (4) references, (5) exhibits and illustrations, and (6) an annotated bibliography. FOREWORD

The Automotive Safety Foundation and the Highway Users Federation for Safety and Mobility have long sought to improve and expand highway safety programming through the funding of manpower research and development projects. The sponsorship of this manual is a further effort to increase the supply of fully prepared highway safety workers through the development of instructional resources.

The Foundation was indeed fortunate to have the Traffic Institute, Northwestern University, and the American Association of Motor Vehicle Administrators serve as contractors for developing and reviewing this instructors manual. We are indebted to them for their valuable technical competence and experience, productive organizational talent and dedication to the field of traffic safety.

D. Grant Mickle
President
Highway Users Federation
for Safety and Mobility

20303

PREFACE

Public Law 89-563 was passed by the 89th Congress and then approved by Lyndon B. Johnson on September 9, 1966. The opening paragraph of Public Law 89-563 states: "Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, that Congress hereby declares that the purpose of this act is to reduce traffic accidents and deaths and injuries to persons resulting from traffic accidents. Therefore, Congress determines that it is necessary to establish motor vehicle safety standards for motor vehicles and equipment in interstate commerce; to undertake and support necessary safety research and development; and to expand the national driver register." Following this opening pre-amble is Title I - Motor Vehicle Safety Standards.

Public Law 89-564 was also passed and was subsequently approved by President Johnson on September 9, 1966. This law is a sequel to the National Traffic and Motor Vehicle Safety Act of 1966 (Public Law 89-563) and is identified as the "Highway Safety Act of 1966."

Section 401 of the Highway Safety Act (Public Law 89-564) directs and authorizes the Secretary of the Department of Transportation to assist and cooperate with other federal agencies,

20304

state and local governments, private industry and other interested parties in increasing highway safety. The Congress then, in Section 402 of the same law, says in part:

> "(a) Each state shall have a highway safety program approved by the Secretary, designed to reduce traffic accidents and deaths, injuries, and property damage resulting therefrom. Such programs shall be in accordance with uniform standards promulgated by the Secretary. Such uniform standards shall be expressed in terms of performance criteria. . . . In addition, such uniform standards shall include, but not be limited to, . . . vehicle registration, operation and <u>inspection</u>." (emphasis added)

The passing of these acts and the subsequent organizing of the National Highway Safety Bureau gave emphasis and impetus to the States' Periodic Motor Vehicle Inspection Programs. At the time of this writing there are 31 states with a periodic motor vehicle inspection program, 8 states are operating random spot inspection programs, and 11 states are still without such a program.

The National Highway Safety Bureau (NHSB), in releasing its first 13 standards, identified Periodic Motor Vehicle Inspection as Standard 4.4.1. The purpose of this standard, according to the NHSB, is to increase the likelihood that every vehicle operated on the public highways is properly equipped and is being maintained in reasonable safe working order.

Safety Rules for the Crucible Furnace

1. Always use care in the foundry area. Crucibles, equipment, flasks, and castings may be hot.

2. Ask your teacher to check your mold before closing it. Make sure it is not too damp or too dry before pouring.

3. Keep molds covered until ready for pouring.

4. Before handling molten metal don protective clothing, including face shield, apron, leggings, and gloves.

5. Keep flammable materials away from the foundry area.

6. Practice lifting and pouring with a cold, empty crucible. Run through the entire procedure several times.

7. Light furnace only when and as directed by your teacher. Follow the manufacturer's directions or the following:
   - A. Purge the furnace by running air for two minutes with gas off.
   - B. Turn off air.
   - C. Place a lighted piece of paper in the furnace.
   - D. Create draft by turning on air slowly.
   - E. Turn on gas slowly. If flame is blown out, go back to A.
   - F. Adjust flame so that all fire is contained within the furnace.

8. Preheat metal to remove moisture before placing it in a crucible containing molten metal.

9. Preheat skimmer before using it.

10. Shut off GAS FIRST, then the air, when finished.

11. Carry ladles and crucibles close to the floor to reduce danger.

12. Mold should be placed only on the floor, never on a bench.

13. If floor is concrete, have someone standing by to shovel foundry sand on spills. Concrete explodes violently when heated.

14. Keep water and wet items away from the foundry area.

15. Allow castings to cool before breaking them out of molds.

16. Two precautions in using polystyrene (Styrofoam) patterns.
    - A. Once pouring is started, keep sprue basin filled to prevent polystyrene from firing back through the sprue.
    - B. Do not breathe the fumes from the burning polystyrene.

17. Completely empty crucible. Solidfied metal will crack the crucible when reheated. Use ingot molds rather than pouring a puddle in the sand.

100006

The Automotive Safety Foundation (ASF), which subsequently combined its operation with Auto Industries Highway Safety Committee and the National Highway Users Conference to form "The Highway Users Federation for Safety and Mobility", recognized that the NHSB Standard for Periodic Motor Vehicle Inspection re-emphasized the need for supervisory and management training in the PMVI field. ASF approached the Northwestern University Traffic Institute and the American Association of Motor Vehicle Administrators (AAMVA) offering to underwrite the cost of developing a manual for instruction in "Administration and Supervision of Periodic Motor Vehicle Inspection." The Traffic Institute and AAMVA agreed to develop the manual. Under the terms of the agreement the Traffic Institute staff would assemble the material and prepare the manual. AAMVA agreed to provide material and consulting service. Louis Spitz, AAMVA Executive Director, Preston Poore and Arthur Tritsch of the AAMVA staff were most cooperative in providing this service. Our completed work was reviewed by AAMVA staff.

No work of this magnitude could be completed without the contributions of many people. There were a number of organizations and officials with an interest in motor vehicle inspection who provided material for this project.

20306

TEACHING & TESTING

The purpose of teaching is to bring about a certain desired behavioral change in an individual. The purpose of testing is to measure the extent and duration of the desired behavioral changes. Learning is said to have occurred when the desired behavioral change is observable or measurable. Thus, we may say that a teacher has taught when he helps his students to learn.

In any teaching situation, then, the teacher's job is to get the student to make the desired behavioral change. This may best be accomplished through the following steps:

1. Identify the terminal behavioral objective[1];

2. Help the student achieve the desired terminal behavior by presenting him with related information, encouraging the necessary physical and mental activity, requiring a particular response to a given stimulus and reinforcing the correct response;

3. Test the student's ability to perform a given behavioral task; and

4. Recognize the student's attainment of the desired terminal behavioral objective.

Perhaps the two greatest challanges to the teacher are, (1) clearly identifying the desired behavioral objectives of a lesson, or the terminal behavioral objectives of a course, and

---

[1] Terminal behavioral objectives are those competencies which the learner is expected to acquire as a consequence of successfully completing the entire instructional sequence.

(2) measuring the student's achievement of the desired behavioral objectives.

To aid the instructor in his efforts to achieve the purposes of this Three Week Course in Administration and Supervision of Periodic Motor Vehicle Inspection, the Federation commissioned Dr. Henry H. Walbesser and his staff at the Bureau of Educational Research, University of Maryland to analyze the instructional purposes of this manual and write appropriate behavioral objectives and measurement criteria.

To effectively utilize Dr. Walbesser's work in the teaching of this course, the instructor should know that in addition to the course terminal behavioral objectives, three distinct classes of intermediate behavioral objectives are given. They are:

a) Process Objectives - those competencies in which the learner acquires a series of actions that constitute a procedure.

b) Product Objectives - those competencies in which the learner constructs a tangible item.

c) Management Objectives - those competencies in which the learner acquires organizing, directing, or controlling skills.

Process, product, and management objectives all mediate to the terminal objectives. The instructional model embedded in the lessons can be depicted by the following schematic:

Because of the interlocking nature of the instructional materials in this course, specific lesson by lesson behavioral objectives were deemed inappropriate. However, general objectives containing the related elements of each class of objective are given in the introduction of each instructional unit.

Behavioral Objectives and Measurement Criterion

To gain maximum results from each instructional unit, the teacher should relate the general objective given for each subject to one or more of the following intermediate or terminal behavioral objectives. Once the relationship has been clearly established, the teacher may employ the criterion measures given under those specific objectives to determine the student's success in achieving the desired behavior.

Intermediate Objectives

PROCESS OBJECTIVES

A. Upon completion of the lessons the course participant will be able to distinguish inter-dependency from independence of a vehicle inspection program and other highway safety activities.

B. Upon completion of the lessons the course participant will be able to identify missing legal or operational components in a given PMVI system and describe the reasons why each identified component is needed.

C. Upon completion of the lessons the course participant will be able to distinguish among the types of motor vehicle inspection according to a given set of functions.

D. Upon completion of the lessons the course participant will be able to demonstrate the use of selection procedures for obtaining supervisors.

E. Upon completion of the lessons the course participant will be able to demonstrate procedures for obtaining public and governmental support for a motor vehicle inspection program.

PRODUCT OBJECTIVES

A. Upon completion of the lessons the course participant will be able to describe the rationale and the data supporting each component of a motor vehicle inspection program.

B. Upon completion of the lessons the course participant will be able to describe federal programs related to motor vehicle inspection and the particular contributions of each.

C. Upon completion of the lessons the course participant will be able to describe the 20th century history of motor vehicle inspection.

D. Upon completion of the lessons the course participant will be able to identify and name the various functions of a motor vehicle inspection program in a state level highway safety program.

E. Upon completion of the lessons the course participant will be able to describe the components of a training program for supervisors and the reasons in support of each component.

F. Upon completion of the lessons the course participant will be able to describe the components of a state owned and operated motor vehicle inspection program and the reasons in support of each component.

G. Upon completion of the lessons the course participant will be able to describe the advantages and disadvantages of a state owned and operated motor vehicle inspection program.

MANAGEMENT OBJECTIVES

A. Upon completion of the lessons the course participant will be able to demonstrate management procedures related to training functions.

B. Upon completion of the lessons the course participant will be able to demonstrate management procedures related to planning and direction functions.

C. Upon completion of the lessons the course participant will be able to demonstrate management procedures related to the delegation of responsibility and control functions.

D. Upon completion of the lessons the course participant will be able to demonstrate management procedures related to budget construction and monitoring.

E. Upon completion of the lessons the course participant will be able to apply the enforcement rules to a given collection of situations within a specific PMVI system.

F. Upon completion of the lessons the course participant will be able to distinguish between appropriate and inappropriate management decisions given a list of problem-management action pairs.

Terminal Objectives

A. Upon completion of the three week course, the course participants will be able to demonstrate procedures for the administration and supervision of a motor vehicle inspection program at the state level or for a political subdivision of a state, given the description of the components of an existing PMVI system.

Criterion Measure - Present the learner with two administrative decisions and two supervisory decisions to be made within a specific PMVI system. The learner should be asked to show what decisions and actions he would take. An acceptable response requires four decisions that would resolve the problems for that particular system.

B. Upon completion of the three week course, the course participant will be able to construct an operational system of motor vehicle inspection for a state or political subdivision of the state, given sufficient demographic and highway information.

Criterion Measure - Give the learner the description of a state or local government with all of the necessary demographic and highway information and ask him to construct an operational motor vehicle inspection system. An acceptable response requires the creation of a PMVI system that is feasible within the information provided.

Periodic Motor Vehicle Inspection is an essential element in the total highway safety program. To successfully carry out this element of the program, administrative and supervisory personnel must be trained that can direct and manage the people, equipment, facilities, and other resourses needed to perform the inspection tasks.

The teacher charged with the responsibility for training PMVI personnel plays a vital role in the total highway safety effort. Through this manual, the Highway Users Federation hopes to provide instructional materials and guidelines that will enable the teacher to bring about the desired behavioral change in each of his students.

Safety Rules for the Metal Lathe

1. General

   A. Dress properly. Remove tie and jewelry and roll sleeves up.
   B. Make adjustments only when machine is completely stopped.
   C. Make sure all guards are in place.
   D. Ask your teacher to check your setup.
   E. Always remove chuck key or wrench immediately after using it.
   F. Be sure all parts of the carriage will clear any rotating part during full-length of cut.
   G. Set tool on center of work to be turned.
   H. Keep your hands on the controls or at your sides except when filing and polishing. Don't lean or lounge on the machine.
   I. Do not pull chips or brush chips away with your hands.
   J. Finish cuts that are close to chuck or against a shoulder by hand feed.
   K. Allow lathe to stop before reversing. Do not "jog" the reverse button to stop lathe.
   L. Remove tool holder or tool post before filing or polishing.
   M. Do not leave lathe while it is running.
   N. Chatter indicates that something is wrong. Check!
   O. Regulate feed, speed, and depth of cut according to size and type of material.
   P. Use proper coolant.
   Q. Make sure tool bit and tool post are secure.
   R. File and polish with right arm arching over work.

2. Between-Centers Turning

   A. Use only safety-type dogs to drive work
   B. Clamp tailstock securely
   C. Adjust & lubricate dead center.
   D. Use properly ground tools.
   E. Use steady or follower rest if needed.

3. Chuck and Faceplate Turning

   A. Place a board under chuck or faceplate during installation or removal. Keep your fingers clear.
   B. Make sure work is securely mounted.
   C. Counterbalance work if needed to prevent vibration.
   D. Turn through one complete revolution to check clearances.
   E. Stand to one side of revolving faceplate.

0004007

SUBJECT: PURPOSES AND OBJECTIVES OF MOTOR VEHICLE INSPECTION

HOURS: 4

OBJECTIVES: To acquaint the student with the historical development of motor vehicle inspection programs; develop an understanding of the various types of inspection programs; create an awareness of the role of vehicle inspection in a balanced highway safety program, and the inter-relationships and inter-dependencies of vehicle inspection and other functional highway safety activities.

METHODS OF INSTRUCTION: The primary method of instruction for this unit is lecture. Because the students are actively engaged in motor vehicle inspection programs, the instructor should stimulate class participation to the fullest extent.

Several of the references, especially numbers 1 and 7, contain charts and tables that can easily be utilized as visual aids by the instruction.

INSTRUCTOR'S GUIDE

(PURPOSES AND OBJECTIVES OF MOTOR VEHICLE INSPECTION)

I. INTRODUCTION

A. Instruction should provide the students with an understanding of the growth and development of vehicle inspection programs in this country. The student should be made aware of the various types of existing programs and the reasons why jurisdictions adopted one program in favor of another or in some cases why no inspection program exists.

The importance of motor vehicle inspection in a balanced highway safety program should be emphasized. The students should understand how vehicle inspection can support other accident prevention measures and conversely, how other preventive measures support vehicle inspection.

20317

	REFERENCES
II. PRESENTATION	
A. <u>Historical Development of Motor Vehicle Inspection</u> - Vehicle inspection has been a part of our society as an accident prevention measure since the late 1920's.	Ref. #1 - pp. 1-18 Ref. #2 - p. 23 Ref. #3 - pp. 1-6 Ref. #5 - pp. 11-29
1. Voluntary inspection programs were initiated in 1926 in Massachusetts, and the next year in New York and Maryland. In 1928 and 1929 Pennsylvania, New Jersey and Delaware also instituted voluntary programs.	
2. The first legislation requiring compulsory inspection of motor vehicles was enacted in 1929 and 1930 by Pennsylvania, Maryland and Massachusetts. By 1940, sixteen additional states adopted compulsory inspection legislation. However, two states, Arkansas and Nebraska, repealed the legislation shortly thereafter.	
3. During World War II several inspection programs were abandoned or sharply curtailed. In some states, such as Connecticut, Maryland and Washington, the programs were never revived.	

	REFERENCES
4. The development of compulsory inspection programs between 1945 and 1967 was somewhat slack in that only nine states enacted legislation during that period. One, Arizona, discontinued its program after two years. By 1967, 21 states and the District of Columbia had compulsory motor vehicle inspection programs.	
5. In 1967 the U. S. Department of Transportation, under the authority of the Highway Safety Act of 1966, issued a standard calling for each state to institute a vehicle inspection program. During 1967, 11 additional states enacted legislation which established a compulsory, periodic inspection of motor vehicles. As of January 1969, 31 states and the District of Columbia had motor vehicle inspection programs that required inspection of virtually all registered motor vehicles in their jurisdictions.	

20319

	REFERENCES
B. Types of Motor Vehicle Inspection Programs - There are basically three types of vehicle inspection programs in existence in the U. S. today.	Ref. #1 - pp. 7-18 Ref. #2 - pp. 15-16 Ref. #6 - pp. 1-3 Chapter IV Ref. #7 - pp. 35-54
1. State owned and state operated. New Jersey and Delaware, and the District of Columbia have adopted this type of inspection system. Under this system the state buys or leases land and buildings, purchases or leases equipment, employs supervisors and inspectors and has complete responsibility for and control of the entire operation.	
a. Some of the advantages of this type of system are:	
(1) Re-inspection provides a quality check on vehicle repairs.	
(2) Inspectors do not personally benefit from any repairs that may have to be made.	
(3) Uniformity of inspections throughout the state is facilitated.	

	REFERENCES
(4) Training of inspectors and supervision of inspections is made easier.	
(5) Collection of accurate and uniform motor vehicle inspection data is facilitated.	
b. Disadvantages	
(1) High cost of implementing and maintaining equipment and facilities.	
(2) Limited number of stations can cause excessive inconvenience to the public due to excessive driving distances and waiting times due to over-crowded facilities.	
(3) State unable to adequately compete with private enterprise for inspection personnel.	
(4) Has only been proven satisfactory and immediately feasible in places with small geographical areas and dense populations	

20321

	REFERENCES
and motor vehicle registration rates.	
2. Private Owned and State Supervised - 29 states have instituted this type of inspection system. Under this system the state licenses and certifies private garages, service stations, automobile dealers, etc., to conduct motor vehicle inspections in accordance with regulations established by the state. The state in turn supervises the inspection activities of the private stations.	
a. Some advantages of this type of system are:	
(1) Large number of stations may be authorized, which provides the motorists with greater convenience by reducing travel and waiting time.	
(2) Programs can be quickly implemented due to facilities, equipment and personnel already being in existence. Also this eliminates the need to select	

	REFERENCES
and train a large inspection force.	
(3) Repairs can be made immediately.	
b. Disadvantages	
(1) Adequate supervision of large numbers of stations is extremely difficult.	
(2) A lack of confidence by motorists because the inspection stations may benefit from repairs.	
(3) Lack of uniformity of inspections between stations because of their large numbers.	
3. Random or Spot Inspections - Under this system state law enforcement personnel set up temporary roadside testing equipment and stop passing motorists and perform vehicle inspections. Eight states have adopted this type of system.	
a. Some of the advantages of this system are:	
(1) Costs will be low because there	

	REFERENCES
is no need to purchase buildings and train large numbers of inspection personnel.	
(2) Motorists will voluntarily keep their vehicles in a safe condition due to the possibility of being subjected to an inspection at any time.	
(3) Provides an opportunity for other official activities relating to drivers, such as checking driver licenses.	
b. Disadvantages	
(1) Only a small percentage of the registered vehicles can be inspected.	
(2) The motorist may be subjected to delays and other inconveniences because he does not know when his vehicle may be inspected.	
(3) Inspections are not as thorough or complete as those done in garages.	

20324

	REFERENCES
4. Combination of Systems - Under this system the best of each type program would be drawn together to overcome the weaknesses of any one type. The state owned and state operated system would be utilized in the heavily populated metropolitan areas and the privately owned and state supervised would be utilized in the less populated areas. Both of these programs would be supplemented with a random or spot inspection system which would help insure voluntary maintenance of vehicles at all times rather than just when it is time for an inspection.	
C. Vehicle Inspection and Accident Prevention - A balanced highway safety program must deal with the highway, the vehicle, and the human element. Motor vehicle inspection is the primary means currently available to government to deal with the vehicle.	Ref. #1 - pp. 36-60 Ref. #1 - pp. 5-14 Ref. #4 - All Ref. #7 - pp. 63-68
1. It can generally be said that the primary objective of motor vehicle inspection is to prevent accidents and reduce deaths and injuries resulting therefrom by detecting and requiring correction of	

Safety Rules for the Milling Machine

1. Make setup and adjustments only when machine is stopped.
2. Make certain work is properly mounted. Use soft hammer or mallet to seat work against parallels.
3. Ask your teacher to approve your setup.
4. Make sure cutters are sharp. Handle them carefully.
5. Set proper feed, speed, and depth of cut.
6. Disengage handles when on automatic feed.
7. Be sure cutter is turning in the proper direction. Feed against the cutter--not with it.
8. Use a brush to remove chips with machine off.
9. Use proper coolant.
10. When finished, turn off machine, release automatic feed controls and clean up.

C002008

	REFERENCES
vehicles with mechanical defects that impair safe operation.	
2. A vehicle inspection program must depend on and receive support from other highway safety functional programs if it is to be effective.	
a. Police traffic services. Vehicle equipment regulations must be enforced by state and local police agencies. Data gathered by the police at accident scenes should reflect to the extent possible the role that vehicle defects played in the accident. The police, through their enforcement powers, must ensure that vehicles have valid inspection stickers, properly displayed, etc.	
b. Traffic courts. The judiciary must be willing and able to prosecute and adjudicate vehicle equipment violations and violations of other regulations pertaining to the inspection of motor vehicles.	
c. Vehicle registration. The vehicle	

	REFERENCES
registration function assists and supports the vehicle inspection program by providing information on vehicle density; geographical distribution; vehicle make, model, age, identification number; and names and addresses of vehicle owners. Registration can be an extremely valuable adjunct to motor vehicle inspection if it requires that a vehicle must have a valid inspection sticker before it can be registered.	
d. Traffic records. Traffic records, especially accident and enforcement reports, provide the information needed to evaluate and upgrade the motor vehicle inspection function. Record systems capable of providing comparisons between such things as vehicle equipment failures resulting in accidents and inspection data can provide quality checks on the inspection program.

SUBJECT: DEVELOPING SUPPORT FOR VEHICLE INSPECTION

HOURS: 4

OBJECTIVES: Improve the student understanding of the need for gaining and maintaining official and public support for motor vehicle inspection programs and improve his understanding of techniques for obtaining or improving support.

METHODS OF INSTRUCTION: The primary method of instruction should be class discussion with the instructor serving as the discussion leader. Students from jurisdictions where inspection legislation failed several times before passage and/or from jurisdictions where there have been attempts to repeal the inspection program should report on who opposed the legislation, why it was opposed, and the reasons behind the eventual success.

Students should be required to develop case histories of the emergence and growth of vehicle inspection in their states with emphasis on the success or failure of public support activities. These cases should be reproduced for the benefit of all students.

INSTRUCTOR'S GUIDE

(DEVELOPING SUPPORT FOR MOTOR VEHICLE INSPECTION)

I. INTRODUCTION

A. Instruction should provide the students with a basic understanding of the need for planned public support activities. Students should be made aware of the controversial nature of compulsory inspection programs and the potential sources of opposition.

The importance of enlisting the support of government officials, news media and organizations should be stressed, including techniques that have been utilized in gaining and maintaining this support.

20221

	REFERENCES
II. PRESENTATION	
A. <u>Need for Public Support</u> - Whether a state will have a motor vehicle inspection program and how effective it will be depends largely on the acceptance and support it receives from drivers and vehicle owners.	Ref. #3 - All Ref. #8 - All
1. In contrast to many other domestic problems, there has not been a great public outcry for more and better highway and traffic safety programs. This is especially true of compulsory vehicle inspection.	
2. Vehicle inspection is the type of program that a large number of people feel they could easily do without. Lack of support for motor vehicle inspection is illustrated by the following:	
a. Several states instituted inspection programs that were later abandoned and never revived.	
b. Prior to the Federal standard requiring state motor vehicle inspection programs, less than half of the states had inspection programs.	

	REFERENCES
c. Even with the Federal standard, only 11 of the 29 non-inspection states instituted inspection programs.	
d. Bills to repeal or modify inspection programs are regularly introduced in the legislative sessions of several states.	
e. The inspection programs in many states frequently come under attack by the news media.	
f. Elected officials in several states feel that to support vehicle inspection would be political suicide.	
B. <u>Developing Public Support</u> - The degree of public support for vehicle inspections is entirely dependent on the quality of the inspection program. The best organized support program cannot overcome the failures of a poorly planned, understaffed, and inadequately financed program. In short, public support is 90 percent dependent on what you do and 10 percent dependent on what you say you did.	Ref. #5 - pp. 5-6

20333

	REFERENCES
1. The first step toward public support is understanding. The public must be provided with information concerning the need for vehicle inspection.	
2. Responsibility for collecting and disseminating information to the public concerning vehicle inspection is shared three ways. a. By government officials with highway transportation responsibilities. b. By the news media, including newspapers, radio and television, industrial, trade and other publications, outdoor advertising, etc. c. By organizations interested in the motor vehicle and its use, including safety councils, professional, civic, religious, fraternal, civil rights and women's groups, and business and industrial organizations.	
3. The Governor's office should play the key role in coordinating the public	Ref. #4 - pp. 15-19

20334

	REFERENCES
support activities of these groups. The governor or his representative should establish a fact-gathering or study committee. The committee should have representatives from each group (governmental, public media, and organizations). a. The group should gather all available information about motor vehicle inspection. This should include: (1) The number of accidents in which defective vehicles were a contributing factor. (2) Facts concerning vehicle defects that were detected in voluntary inspection programs. (3) Accident and fatality rates of states with inspection programs as compared to those without. (4) Previous unsuccessful attempts to institute inspection programs -- who supported those efforts, who was opposed, why the attempts failed, etc.	

20335

Safety Rules for the Metal Shaper

1. Make adjustments only with machine stopped.
2. Set work against parallels with soft hammer or mallet. Clamp securely.
3. Select and insert properly ground tool in holder.
4. Be sure that ram and head will clear the work and holding devices.
5. Start motor with control lever in neutral.
6. Keep hands away from cutting tool and moving parts.
7. Flying chips can be controlled by rigging a screen.
8. Use proper coolant.
9. Do not leave machine while it is running.
10. When finished, remove tool and clean up the area.

2009

	REFERENCES
b. The study committee should also gather data as to the type of program that would be most suitable for and acceptable to the motorists of the state.	
(1) The two most important factors in this regard are <u>motorist convenience</u> and <u>program costs</u>.	
4. States that have a motor vehicle inspection program should establish an advisory committee to serve as a sounding board for and a support group to the inspection program administrator.	
a. This committee should consist of representatives from each group and should be kept informed of any proposed changes in the program.	
b. Their advice should be sought on proposed changes in inspection regulations.	
C. <u>Developing Official Support</u> - To operate effectively, a vehicle inspection program must have the understanding and support of public officials with highway safety responsibilities at the state and local level.	

20336

	REFERENCES
1. Public officials who play a significant role in the success or failure of the program include: highway and traffic engineers, police, driver educators, judges, prosecutors, health officers and driver license officials. a. The public generally considers these officials "in the know" on highway safety matters, and derogatory remarks about the inspection program by them can curtail public support.	
2. Oftentimes these officials are not personally convinced of the value or need for an inspection program. Also, an inspection program is or will be another competing force for the tax dollar.	
3. To help overcome apathy or resistence, officials should be: a. Provided with facts concerning the need for an inspection program in the state. b. Asked for counsel and guidance in determining the best type of program including who will inspect,	

	REFERENCES
where, when, how often, what items, etc.	
c. Kept informed throughout the planning implementation stages on decisions that are being made or considered.	
d. Should be asked to serve on committees that are developed to study motor vehicle inspection in the state.	
D. <u>Developing Media Support</u> - Since an effective motor vehicle inspection program depends to a large extent upon a public that is informed of the problem and understanding of the needs, it is extremely important that the program have the support and backing of the news media.	Ref. #4 - pp. 25-26
1. Media people can make or break the inspection program.	
a. There have been several cases illustrating how a hostile news media can turn public opinion against motor vehicle inspection. This is especially true where they were not provided facts on the	

20338

	REFERENCES
need for inspection or information on how the program would operate. (1) A good working relationship must be developed with the media. A frequent complaint by the media is that they are only consulted when something is wanted. (2) The media should be involved in the planning of the program and their advice on such matters as to what type of inspection program should be adopted, how it should be operated, what items will be inspected, etc., should be sought. ASK THEM FOR HELP, DON'T TELL THEM. (3) The media should also be provided with information after a program has been instituted. This should include information concerning any changes that are being made or considered in the operation of the program as well as possible changes in items to be inspected.	

20339

	REFERENCES
They should also be provided with the reasons for the proposed changes.	
b. Where the media are not in support of inspection, it is not uncommon for reporters to take a vehicle to several inspection stations within a state to show that inconsistencies between inspection stations exist. The media should not be discouraged from doing this, but they should be asked to provide officials with their findings before airing them to the public.	
(1) The state in turn must be prepared to conduct swift investigations of these complaints and take necessary action when justified.	
(2) This activity by the state will build confidence in the integrity of the program.	
2. The National Safety Council, in their publication, "How to Promote Motor Vehicle	Ref. #4 - p. 26

	REFERENCES
Inspection in Your State," offers the following suggestions for utilizing the resources of radio and television. a. See that the news departments of your radio and television stations are included in the distribution of news releases about the inspection program. b. Take advantage of the growing trend toward editorializing in radio and television. Much of this editorial activity has been in the traffic safety area. This provides opportunity for promotion of the vehicle inspection program. c. Provide local stations with spokesmen who can be interviewed or participate in talks over the air, and provide the local stations with information about the inspection program. 3. Because of the special expertise of the media people their assistance should be	

20341

	REFERENCES
sought in developing special pamphlets, flyers and posters that are necessary supplements to regular channels of communication. a. Innovative ways of distributing this type of information should be explored. (1) The groups which are supporting the inspection program may include items with their regular mailings. (2) May be able to include in mailings of vehicle registration notices. (3) Supply of flyers and brochures can be put in such places as police stations, doctors' offices, barber shops, and other places where people are likely to be. (4) May be taken as a special project for organizations, such as Boy Scouts or Girl Scouts.	

	REFERENCES
E. Developing Organization Support - Every state has several organizations or groups that play a significant role in influencing public opinion.	Ref. #1 - All Ref. #2 - All Ref. #4 - p. 22 Ref. #6 - p. 8
1. Every effort must be made to identify all of the organizations in the state whose cooperation and support is needed.	
a. These organizations should be given all of the available facts concerning the need for a vehicle inspection program.	
b. Their advice and counsel should be sought concerning the best type of inspection program, how it should operate, what items should be inspected, etc.	
2. The organizations should be invited to actively participate in the public support program.	
3. It is important to identify those groups that are most likely to oppose a vehicle inspection program.	
a. A concerted effort must be made to swing these people over to your side.	

	REFERENCES
One of the most successful ways to accomplish this is to involve them as much as possible.	
b. Opposing groups should be invited to participate in the overall planning of the program, to participate in discussions on the pros and cons of the various types of inspection programs, etc.	
c. Recent experiences in some states have identified the types of organizations or groups that frequently oppose vehicle inspection.	Ref. #7 - pp. 76-77
(1) Farm Organizations - Their support is a "must" for political success in many states. Farmers and ranchers are used to having a great deal of freedom when it comes to the type and condition of equipment they operate on public highways. Any regulation that is likely to impose added restrictions on this freedom is likely to be opposed.	

20344

	REFERENCES
(2) Civil Rights Organizations - In recent years the political clout of civil rights organizations has grown tremendously. These groups frequently view vehicle inspection as discrimination against the poor. The case that is usually made is that inspection provides no inconvenience to the upper and middle-income groups because they are likely to drive newer vehicles that easily meet inspection standards. The lower income groups, however, drive older vehicles that are frequently in need of repairs and least likely to meet inspection standards. Because of inadequate public transportation, lower income wage earners often have no way to get to work except in older vehicles which, in order to pass minimum inspection standards, would require prohibitive repair costs.	

Safety Rules for the Arc Welder

1. Wear approved welding helmet or face shield. Do not use gas welding goggles for arc welding!

2. Wear treated gauntlet gloves, leather apron and leather jacket.

3. Wear safety glasses under welding hood if intermittently chipping and welding.

4. Do not breathe fumes. Make sure exhaust is working.

5. Keep flammable materials away from welding area.

6. Use a welding screen to prevent flashing others.

7. Report to your teacher if electrode holder, ground clamp, connections, or cables get hot.

8. Hang up electrode holder. Do not lay it on grounded bench.

9. Use "HOT" sign on work and table.

10. Be careful of others when welding and chipping.

11. Dispose of rod ends in the proper container. Do not allow them to get on the floor.

1498
2018

	REFERENCES
d. In public support programs the two organizations described above should be given the utmost consideration. Facts should be gathered and presented in a manner that will demonstrate what inspection will do FOR these people rather than TO them. (1) The quickest way to alienate these groups is by making inspection procedures too strict at the onset of the program.	
4. There are numerous activities that groups and organizations can engage in which will help develop and maintain public support for vehicle inspection. *a. Supporting resolutions - the organizations should be asked to go on record in support of vehicle inspection by adopting a resolution so stating.	

*Sample - Resolution, Open letter, Press release, and Speech are attached.

	REFERENCES
(1) Copies of the resolution should be sent to legislators, news media, other organizations and various other public officials.	
(2) The resolution as well as the organization's reason for supporting the program should be published in the organization's publication.	
b. Individual members should be urged to write personal letters to the governor and appropriate state legislators.	
(1) It should be noted that form letters <u>should not</u> be used for this purpose. Mass produced letters carry little weight with public officials.	
5. The administrator can stay alert to public attitudes toward his program by establishing a simple reporting procedure in which mechanics and station operators could easily report on the types of complaints and comments that they hear about the	

	REFERENCES
inspection program. a. This technique will enable the administrator to discover unpopular policies before they develop into full fledged problems. b. It also provides guidelines on those things that need to be clarified to the motorist. This provides a good basis for news releases and training bulletins.

SUBJECT: FEDERAL PROGRAMS

HOURS: 3

OBJECTIVES: To develop an understanding of the various federal programs that relate to new and used vehicle standards; how these programs relate to state vehicle inspection programs; the objectives, requirements and benefits of the federal programs.

METHODS OF INSTRUCTION: Instruction should consist of combination lecture and class discussion. Students should be encouraged to explore and explain how their inspection programs may have to change as a result of the Federal standards.

INSTRUCTOR'S GUIDE

(FEDERAL PROGRAMS)

I. INTRODUCTION

A. Instruction should provide the student with a working knowledge of the various Federal programs that both directly and indirectly relate to state motor vehicle inspection programs. Students should understand the objectives of Federal programs and the role that state periodic motor vehicle inspection plays in assuring the attainment of these objectives.

Emphasis should be placed on the inter-relationships and inter-dependencies of Federal and State programs designed to insure that motor vehicles are equipped and maintained in a safe operating condition.

20352

	REFERENCES
II. PRESENTATION	
A. <u>The Federal Role in Vehicle Inspection</u>	
1. Prior to the 1960's, it was generally felt that governmental responsibility for traffic and highway safety was almost entirely vested at the state and local level.	
2. During the 1960's, the Federal role in highway and traffic safety has been more clearly defined and expanded.	
a. The Federal responsibility for improving the safety qualities of motor vehicles and vehicle equipment is an area of particular concern.	
3. In 1966, the President of the United States signed two pieces of safety legislation into law -- the Highway Safety Act and the National Traffic and Motor Vehicle Safety Act. Both Acts require a coordinated Federal/State effort in developing and implementing vehicle safety performance standards for both new and used vehicles.	
a. These two laws give the U. S. Department of Transportation the authority	

	REFERENCES
and the responsibility to assume a leadership role in the national traffic safety effort.	
4. The National Traffic and Motor Vehicle Safety Act states that "in order to assure a continuing and effective national safety program, it is the policy of Congress to encourage and strengthen the enforcement of state inspection of used motor vehicles."	Ref. #1 - All
a. The Act further directs the Secretary of Transportation to "conduct a thorough study and investigation to determine the adequacy of motor vehicle safety standards and motor vehicle inspection requirements and procedures applicable to used motor vehicles in each state, and the effect of such programs authorized by this title upon such standards, requirements, and procedures for used motor vehicles."	

	REFERENCES
b. The role that states should play in the formulation of Federal programs under the Act is delineated. (1) The Secretary of Transportation is authorized to cooperate with the states in the planning and development of motor vehicle safety standards and the methods for inspecting and testing to determine compliance. (2) The Secretary is directed to consult with the Vehicle Equipment Safety Commission (which is made up of state officials) in developing motor vehicle safety standards. (3) The Secretary of Transportation is required to establish a "National Motor Vehicle Safety Advisory Council, a majority of which shall be representatives of the general public, including representatives of state and local governments." The Secretary	

Safety Rules for the Oxyacetylene Welder

1. Inspect equipment before using. Make sure tanks are chained or otherwise restrained from falling. Inspect hoses, connections, and valves. Report defects to your teacher.

2. Before changing tanks, place protective cap over valves.

3. Keep equipment clean and free of oil and grease. NEVER oil or grease threads.

4. Make sure ventilation is adequate.

5. Keep flammable materials away from the work area.

6. Wear the proper type of goggles.

7. Release regulator pressure screws. Open cylinder valves gradually.

8. Open acetylene cylinder valve not more than 1/4 turn. Keep wrench in place on the valve so that valve may be shut off quickly.

9. Acetylene pressure in the hose should never exceed 15 pounds per square inch.

10. Use a friction lighter to ignite the torch--never use a match or other lighter.

11. Close acetylene valve first if torch backfires.

12. Point torch away from yourself and others.

13. Keep sparks and flame away from cylinders, hoses, and regulators.

14. Close cylinder valves when finished, release pressure on regulators, and drain lines by opening torch valves. Reclose torch valves.

15. Quench hot metal or mark "HOT" with chalk, soapstone, or a special sign.

2011

	REFERENCES
must consult with this Council on motor vehicle safety standards.	
5. The Highway Safety Act declares that "Each state shall have a highway safety program approved by the Secretary, designed to reduce traffic accidents and deaths, injuries and property damage resulting therefrom." Among other things, the Act calls for the development of uniform standards by the Secretary in the areas of "vehicle registration, operation, and inspection."	Ref. #2 - All
a. The act delineates the role that states should play in formulating Federal programs.	
(1) The Secretary must develop standards in cooperation with the states and their political subdivisions.	
(2) A National Highway Safety Advisory Committee is created. Members are appointed by the President and must include representatives of state and local government including state legislators. This	

	REFERENCES
Committee is responsible for advising, consulting with and making recommendations to the Secretary on matters relating to the highway safety activities of the Department of Transportation. In addition, the Committee is authorized to (1) review research projects and/or programs and make recommendations concerning those having merit and (2) to review and make recommendations on standards prior to their issuance.	
6. The two Acts clearly give the Secretary of Transportation authority to improve the safety qualities of used motor vehicles. Under the National Traffic and Motor Vehicle Safety Act he has the power to issue uniform Federal standards applicable to all motor vehicles in use. Under the Highway Safety Act he has the authority to implement and enforce the used motor vehicle standards by requiring states to institute motor vehicle inspection programs.

	REFERENCES
B. Federal Influence on State Inspection Programs	Ref. #3 - pp. 2-3
1. The most immediate impact on state vehicle inspection programs will result from the periodic motor vehicle inspection standard issued under the Highway Safety Act.	
a. The motor vehicle inspection standard requires that each state have a periodic vehicle inspection program for all registered vehicles or an experimental or pilot program approved by the Secretary. To be in compliance with the standard, the program must:	
(1) Require each vehicle registered in the state to be inspected, either at the time of initial registration and at least anually thereafter, or at such other time as may be designated under an experimental, pilot or demonstration program approved by the Secretary.	
(2) Insure that the inspection is performed by competent personnel specifically trained to perform	

	REFERENCES
their duties and certified by the state. (3) Require inspections to cover systems, sub-systems and components having substantial relation to safe vehicle performance. (4) Establish inspection procedures to equal or exceed criteria issued or endorsed by the National Highway Safety Bureau. (5) Require each inspection station to maintain records in a form specified by the state, which would include at least the following information: (a) Class of vehicle (b) Date of inspection (c) Make of vehicle (d) Model year (e) Vehicle identification number.	

20359

	REFERENCES
(f) Defects by category (g) Identification of inspection (h) Mileage or odometer reading. (6) Publish summaries of records of all inspection stations at least annually, including tabulations by make and model of vehicle.	
b. The motor vehicle inspection standard is supplemented by a Highway Safety Program Manual which provides additional guidance to the states in implementing or improving motor vehicle inspection programs. Specifically, the Manual provides insight into: (1) The purpose of vehicle inspection. (2) The legal authority of the Department of Transportation	Ref. #4 - All

	REFERENCES
to establish motor vehicle inspection program standards. (3) The Department of Transportation's general and specific policies regarding vehicle inspection programs. (4) Methods of developing and operating state inspection programs. (5) Methods of evaluating the quality of vehicle inspection programs. (6) The types and uses of various records and reports. c. Since the passage of the Highway Safety Act, the Department of Transportation has clearly indicated that it will utilize its authority and resources to see that each state institutes a periodic motor vehicle inspection program. Any program that will not result in <u>all</u>

registered vehicles being inspected at least annually is less than satisfactory.	Ref. #6 - All
(1) The Federal Highway Administration, U. S. Department of Transportation, in FHWA Order 7-3 outlines the policies and conditions that must be met by a state if they wish to have an inspection program approved which deviates from the one described in the standard.	
(a) The order will make it difficult, if not impossible, for any program other than a PMVI program to meet the necessary requirements.	
2. The National Traffic and Motor Vehicle Safety Act, while not having an immediate impact on state vehicle inspection programs, will eventually have an effect.	
a. While the department has the authority under this Act to establish uniform Federal standards for used motor	

288

	REFERENCES
vehicles, it has not done so. In December, 1969, the National Highway Safety Advisory Committee reported on a study of the present status of the Department's standards-making program for used vehicles. The Committee stated, "we express our utter dismay at the present stagnation of the Highway Safety Bureau's program to implement the intention of Congress in the matter of used car standards and motor vehicle inspection. We conclude that not one single used car standard can be expected under present conditions for at least several years." The Committee also urged the Secretary of Transportation to sponsor a conference of used vehicle inspection and maintenance which would bring state and federal officials and experts together in order to promote the ideas and techniques of inspection.	Ref. #7 - Resolution on Used Vehicle Safety
b. Once the Secretary starts to exercise the authority vested in him under the	

	REFERENCES
Act, the Federal influence on state inspection programs will be greatly expanded. Where the states currently establish the performance standards that used vehicles must meet, and then enforce these standards through inspections, the Federal government will be establishing the performance standards and the state will retain the enforcement responsibility.	
(1) The Secretary, in his report to Congress, Safety for Vehicles in Use, indicated that the following systems and components are being considered for initial standards for used vehicles:	Ref. #5 - p. 32
(a) Brake systems, including brake lines, service brake system, emergency brake system, and parking brake system.	
(b) Steering and suspension systems.

SUBJECT: LEGAL ASPECTS OF MOTOR VEHICLE INSPECTION

HOURS: 4

OBJECTIVE: To develop an understanding of the legal framework in which a motor vehicle inspection program must operate, including the legislation creating the function and the legal authority granted the administrator to establish and enforce administrative rules and regulations; acquaint the student with appellate court decisions regarding administrative enforcement and civil liability; and to discuss the relationship of the federal and state standards relating to vehicles and vehicle equipment.

METHODS OF INSTRUCTION: The primary method of instruction for this unit is lecture combined with full class discussion and participation. Because the students are actively engaged in vehicle inspection programs, the instructor should attempt to stimulate and encourage full class participation and discussion.

20370

II. PRESENTATION	
A. Creating the Agency	
1. Every governmental agency, bureau, department, division, etc., must point to some law establishing or creating the agency and setting forth the powers and duties to be performed. The Uniform Vehicle Code (1968) recommends the Department of Motor Vehicles be assigned the function of inspection of motor vehicles. The law creating the agency and specifying the duties and powers is a legal framework around which the administrator adopts rules and regulations for the administration and enforcement of the motor vehicle inspection law. This power to make rules and regulations is a very important and necessary aspect of government. The statute establishes guidelines and leaves the details of the operation to the administrator.	Ref. #4, Secs. 2-301 et seq. and 13-101 et seq. Ref. #4, Sec. 13-112
B. Duties of Department	
1. Establish inspection stations (if law provides for state owned and operated	Ref. #4, Secs. 13-105, 13-106, and 13-107

	REFERENCES
stations) or appoint official inspection stations (if law provides for privately owned and operated inspection stations).	
2. Establish list of items to be inspected on vehicles. Some items of equipment are set forth in the statutory law -- brakes, lights, horns, mufflers, mirrors, etc.	Ref. #4, Sec. 13-104; Ref. #3, Exhibit II List of Inspection items; Ref. #2 - All Ref. #4 - Chapt. 12
3. Statute normally establishes the fee charged for each inspection.	Ref. #4, Sec. 13-107
4. Department normally issues or approves all signs, posters, inspection certificates, etc.	Ref. #4, Secs. 13-111 and 13-107
5. Other administrative duties.	
C. Duties of Motorists	
1. It is unlawful to drive or move on any highway any motor vehicle, etc., unless the equipment on such vehicle is in good working order and adjustment and unless the vehicle is in such safe mechanical condition as not to endanger the driver or other occupant or any person or property.	Ref. #4, Sec. 13-101 Ref. #5, pp. 436-441 Ref. #6, Sec. 166

	REFERENCES
2. Unlawful for owner or driver to refuse to submit a vehicle to any inspection and test that is authorized or required.	Ref. #4, Sec. 13-103
3. Every motor vehicle must be inspected periodically, but at least annually, is provision of Uniform Vehicle Code. Some states make it more frequently. Others have adopted random inspection by teams of inspectors who establish roadblocks along the highway.	Ref. #4, Sec. 13-104 Ref. #1, pp. 26-29
D. Administrative Law	
1. For every administrative agency there is a body of law known as administrative law which governs many of the activities of the administrative process.	
2. The work of an administrative agency can be divided into three functions:	
a. Making of rules and regulations -- both for internal operation of the organization and for the general public which it serves.	
b. Regulation or enforcement -- both of statutory law as well as rules	

Safety Rules for the Paper Cutter

1. Be certain that the handle or lever controlling the blade is in its proper position and that the safety lock is engaged before setting back gage.

2. Keep hands clear of blade at all times.

3. Do not overload the cutter--work with smaller batches that cut easily.

4. Use care in jogging stock against the back gage. Paper can cut!

5. Keep both hands on the cutting lever or handle during the cut and return stroke.

6. Be sure handle or lever is in the proper position before reaching for cut stock.

7. Engage safety lock after using the cutter.

SIC 2013

	REFERENCES
and regulations made by agency -- done by inspection and investigation.	
c. Adjudication -- determining when a statutory law or rule and regulation has been violated.	
3. Many states have adopted an "Administrative Procedure Act" which sets forth the procedures by which most administrative agencies adopt rules and regulations. Such laws normally require that the agency give the public notice that a certain rule is being proposed, and sometimes must hold a public hearing. Interested persons can then submit their views either orally at a public hearing, or in writing. When the proposed rule is adopted, the agency must then publish such fact, and in many states file it with some office such as Secretary of State or Attorney General.	Ref. #7, Vol. 4 pp. 397-408
4. The process called adjudication or determining if there has been a violation of a statutory law or rule and regulation normally provides for judicial review of the decision in a court of law. The	

	REFERENCE
appeal from an administrative decision requires: a. That the person must have standing to appeal -- that is, he must have been personally affected or aggrieved by the action of the administrator. b. That the decision of the administrator is final -- there are no other administrative remedies available such as a hearing before an appeal board. There is no such provision in the Uniform Vehicle Code for motor vehicle inspections. The appeal would be directly from the agency to the courts. c. That such appeal will not consider the wisdom of an administrator's decision as long as he has not violated some statutory or constitutional provision, or acted beyond his authority. The administrator's decision must be based on some evidence -- the standard normally used is "substantial evidence". In other words, he cannot be arbitrary or capricious and abuse his discretion.	

	REFERENCES
d. Courts will set aside an administrative decision if the administrator has not followed his own rules and regulations- even if he was not required to make such a rule in the first instance. If he does issue a rule, he must follow it. Vitarelli v. Seaton, 359 U. S. 535, 79 S. Ct. 968 (1959).	
E. Inspection by Police Officers	
1. In addition to the periodic inspection of vehicles, the Uniform Vehicle Code, and many states, provide that police officers "may at any time upon reasonable cause to believe that a vehicle is unsafe or not equipped as required by law, or that its equipment is not in proper adjustment or repair, require the driver of such vehicle to stop and submit such vehicle to an inspection and test..."	Ref. #4, Sec. 13-102 Ref. #1, pp. 42-53
2. If a vehicle is found to be in an unsafe condition or is not in proper repair and adjustment, the officer may issue a written notice to the driver and send copies to the motor vehicle department. In most states	Ref. #4, Sec. 13-102

	REFERENCES
this action requires that the vehicle be repaired and inspected within 10 days. If in the reasonable judgment of the officer the further operation of the vehicle would be hazardous, he can require that it not be operated <u>or</u> that it be driven to the nearest garage or place of safety.	
F. Motor Vehicle Inspection and Constitutional Issues	
1. Arguments that motor vehicle inspection violates the "due process" clauses of both the state and U. S. Constitution (14th Amend.) because inspections are arbitrary, harsh, and an unreasonable exercise of the police power, has been rejected by the courts. City of Evanston v. Wazau, 364 Ill. 198, 4 N.E.2d 78 (1936); Miami v. Slone, 190 So. 810 (Fla. 1939).	
2. Arguments that the creation of a motor vehicle inspection system was an unconstitutional delegation of legislative authority has also been rejected by the courts. City of Evanston v. Wazau, <u>supra</u>. "It is true that while a legislative body cannot divest itself of its proper function	

	REFERENCES
by determining what the law shall be, it may nevertheless authorize others to do those things which it might properly, but cannot understandingly or advantageously, do itself. ... This doctrine is sound and has been adhered to for many years, for the obvious reason that government could not be carried on if nothing were left to the judgment and discretion of administrative officers. ... A clear distinction exists, however, between the power to legislate -- to grant the permit under certain specified conditions -- and the power to administer or regulate its exercise, once granted." See also Brattleboro v. Norwicki, 117A.2d 258 (Vt. - 1955).	
3. Arguments that inspection of vehicles places an unreasonable burden on interstate commerce has been rejected by the courts. Mayer v. Ames, 133 Ohio St. 458, 14 N.E.2d 617 (1938), cert. denied 305 U. S. 621 (1938).	
4. At least eight states have established a random inspection program which involves stopping motorists at a roadblock to check	

	REFERENCES
equipment alongside the highway. Such road-blocks were held to be constitutional in People v. DeLaTorre, 64 Cal. Rptr. 804 (Cal.App.-1967).* The court held it is not a denial of an individual's right of mobility.	
G. Preemption of Vehicle Equipment by Federal Government	
1. In 1966 the U. S. Congress entered the field of motor vehicle equipment by passing the "National Traffic and Motor Vehicle Safety Act of 1966" (15 U.S.C.A. 1381 et seq.). This act provided for the issuance of federal standards concerning motor vehicle performance and equipment.	
2. In Sec. 1392 of that Act it provides for supremacy of federal standards as follows: "(d) Whenever a Federal motor vehicle safety standard established under this subchapter	

*For additional cases on roadblocks, see Fisher, Edward C., Laws of Arrest, Traffic Institute, Northwestern University, 1967, with current supplement, Sec. 38, "Stopping Vehicle to Inspect License, Equipment, or Load," pp. 79-85.

	REFERENCES
is in effect, no State or political subdivision of a State shall have any authority either to establish, or to continue in effect, with respect to any motor vehicle or item of motor vehicle equipment any safety standard applicable to the same aspect of performance of such vehicle or item of equipment which is not identical to the Federal Standard. ..."	
3. This supremacy of the federal standard has been narrowly construed by the federal courts. Examples are the cases dealing with the Chrysler "Super Lite" which is an additional light to the other lighting equipment required by the federal standard. The states of Vermont, New Hampshire and New York found that this super lite was hazardous and prohibited its use under the state equipment standards. Chrysler Corporation brought suite to prevent the states from issuing regulations prohibiting such lights on the ground that the federal standard had preempted the field.	

20381

	REFERENCES
The federal courts held that the federal preemption was limited and it did not bar the states from regulating equipment not covered by the federal standard. The super lite did not impair the effectiveness of the lighting requirements of the federal standards and hence would be regulated by the states. Chrysler Corp. v. Rhodes, 294 F. Supp. 665 (D.C.-N.H.-1968) affirmed 416 F.2d 319 (C.A. 2d-1969); Chrysler Corp. v. Malloy, 294 F. Supp. 524 (D.C.-Vt.-1968) and Chrysler Corp. v. Tofany, 305 F. Supp. 971 (D.C.N.D.-N.Y.-1969) both reversed by 419 F.2d 499 (C.A.2d-1969).	
H. Civil Liability for Motor Vehicle Inspection	
1. The question arises, what if the vehicle is inspected, passed, and a few days later an accident is caused or contributed to by some defective part which has been inspected? Does this give rise to an action for damages against the governmental agency and/or the person who did the inspecting?	
2. First, let us consider the department's liability. As a general rule the government is immune from a lawsuit for torts	Ref. #8, Sec. 125

	REFERENCES
committed by its employees. However, in recent years this doctrine of governmental tort immunity has been changed in a few states. For example, the Federal Government has enacted a "Federal Tort Claims Act" under which a person who has been injured by some negligent act on the part of a Federal employee can sue in the federal courts. Unless the law has been changed by court decision or statute in the particular state, the general rule is that a lawsuit cannot be brought against the motor vehicle department or other government agency. Employees of governmental agencies who perform what is called ministerial acts are liable for their own personal acts which are negligent. (For example, a state employee, driving a motor vehicle in the course of his duties, runs a stop sign, and as a result of his negligent act, another person is injured or property is damaged. The employee would be liable for such acts). However, employees are not liable, generally, if their duties are what the courts call discretionary. That is, the duties involve discretion and	

	REFERENCES
judgment. No court decisions directly in point were found concerning the liability of employees of a state owned and operated motor vehicle inspection station. However, it is likely the courts would hold the employee personally liable if he was negligent in the manner of conducting the inspection and the negligence was the proximate cause of injury to another.	
3. As for a privately owned and operated inspection station which has been officially designated by the state motor vehicle department to conduct motor vehicle inspections, it has been held that where an inspection was negligently done and this was the proximate cause of injury to another, the station is liable. In Buszta v. Souther, 232 A.2d 396 (1967) the Supreme Court of Rhode Island held a service station liable. The vehicle had been inspected and passed. About a month later the daughter of the vehicle's owner was involved in an accident in which she was injured. Suit was brought against the service station on the	Ref. #6, Sec. 166

Safety Rules for the Platen Press

1. Make sure form is securely locked in the bed.
2. Apply ink only when press is at a dead stop.
3. Have your teacher check your setup and supervise your feeding.
4. Make sure guards are in place and functioning.
5. Start at slowest speed. Increase speed only as your skill increases.
6. Never attempt to retrieve a misfed sheet! Use throw-off lever, stop machine and open platen.
7. Stop press before attempting to retrieve paper picked up by the ink rollers.
8. Never leave the press while it is running.
9. When finished, stop press and clean up according to directions.

2014

	REFERENCES
grounds the brakes were in defective condition. The court held there was a legal cause of action and that the liability of the inspection station extended to anyone injured.

SUBJECT: INTRODUCTION TO ORGANIZATION

HOURS: 6

OBJECTIVE: To develop an understanding of some basic principles of management as they apply to the part that organization plays in achieving the goals of a motor vehicle inspection program.

METHODS OF INSTRUCTION: The primary method of instruction for this unit is lecture.

Because the students will be actively engaged in motor vehicle inspection programs the instruction should stimulate class participation to the fullest. This should be done by discussing the organizational structure in which the students now operate and have the class suggest improvements. The students should also be required to participate in practical organizational exercises.

The syllabus highlights management theories which go into an effectively operating organization and which will be recognizable to those students who have been exposed to formal management training. Three attachments are included which should further assist the instructor in preparing for this phase of the training program.

20387

INSTRUCTOR'S GUIDE

(INTRODUCTION TO ORGANIZATION)

I. INTRODUCTION

A. Instruction should provide an understanding of management principles involved in the allocation of functions and responsibilities within an effective motor vehicle inspection program.

It should be emphasized to the student that the motor vehicle inspection segment of state government is big business and must be operated as such under the guidance of knowledgeable administrators and within an organizational structure designed to facilitate the accomplishment of set goals.

20388

	REFERENCES
II. PRESENTATION	
A. An Overview of the Theory of Organization	
1. In order for a periodic motor vehicle inspection program to be successful it must operate within an organization which lends itself to the carrying out of its objectives. This does not mean that vehicle inspection can be the responsibility of a unit of government that is entirely independent of the assistance and cooperation of other agencies, but rather that vehicle inspection should operate within an organizational structure that fits the needs of the program while embodying accepted theories of administration. In organizing a vehicle inspection program, the objective should be to establish an organizational structure within which various degrees of responsibility and authority for making decisions and taking actions are delegated. The objective is to establish responsibility and authority where action can or must be accomplished. The level to which these various degrees of authority and responsibility are	Ref. #1 - par. 2.7.1.

	REFERENCES
assigned establishes the principal echelons within the structure. The lateral division of responsibility or authority establishes the functional organization. This does not mean that the head of an organization can delegate final responsibility. It is a well-established principle of management that the top executive alone is responsible for all that his organization does or fails to do, and that he can best discharge his responsibility through an established chain of command which assists him in this function. The head of a motor vehicle inspection department, working within the framework of an effective organizational structure, should have subordinates that present to him that information which he requires to keep abreast of the current situation and to form the basis of sound decisions. Staff personnel receive information from personal observation, from the head administrator, from other staff employees, from research of files,	
	REFERENCES
records, and studies available, and from reports received from subordinates. They analyze and condense this information in order to present only significant facts. If this is done, the head of the motor vehicle inspection program will not be burdened by undigested or irrelevant information and he will have more time for field trips and personal observation of operating conditions in order to enable him to better guide the program.	
B. Departmentation	
1. It would be impractical to outline an organizational chart to encompass a vehicle inspection program and to expect it to be utilized by every lecturer using this syllabus. The differences in programs, i.e., state-owned, state-appointed, spot-check, combination, now in operation or being adopted by state legislatures, require different organizations. However, an effective organizational structure is necessary to carry out effective programs in order to meet highway safety needs.	Ref. #4 - Chap. IV - p. 4

	REFERENCES
With this in mind, some suggestions can be made.	
2. When placing vehicle inspection activities within an organizational structure, the administrator should consider two management theories of organization charting, namely mechanical (structural) and behavioral. Under the mechanical theory the functions to be performed are decided upon and a chart is drawn placing these functions, in detail, within the structural authority. The premise here is that the functions will be satisfactorily performed, regardless of the personnel involved, and the result will be an efficient organization. The behavioral theory is based on the relationships between humans. This theory suggests that guidelines are not needed -- that it is the individual who is important. As can be seen, an intelligent combination of the two theories should be worked into the organization chart.	
3. When we talk of departmentation we mean any unit, regardless of size, set up for the	

20392

	REFERENCES
purpose of performing a function within proper limits of supervision. Relationships between activities should be considered when grouping units, as should specialization of activity or knowledge required to perform a particular function. Although it is difficult to stress uniformity when dealing with many different political jurisdictions, it is necessary to define some basic terms when discussing organization planning. a. Accountability - is the requirement that the individual answer to his senior for his success or failure in the execution of the duties for which he has responsibility and authority. b. Authority - is the right of power connected with a rank or position to make a decision in fulfillment of a responsibility, and to act, command, or require action by others. c. Delegation - is the granting or conferring of both responsibility and authority from one organizational unit to another.	

20393

	REFERENCES
d. Duties - refer to the tasks which contribute to functions and which a single individual is required to perform.	
e. Formal Organization - is the formal structure and the formally assigned functions/duties.	
f. Function - is one of the processes which, taken together, are designed to accomplish an objective.	
g. Informal Organization - refers to the friendships, group relationships, and customs that grow when people are brought together on a job.	
h. Mission - is the purpose for which the organization exists; the sum of all the more detailed goal formulations.	
i. Organizational Goals - refers to the results an organization desires to attain. The over-all goal is achieved by sub-goals. When talking about goals it is necessary to know if you are talking about the ultimate goal of	

20394

General Safety Rules for Electricity/Electronics Laboratories

1. Consider all wires and terminals as live and "HOT" until proven otherwise by a safe method of testing.

2. Resist the temptation to throw a switch just to see what happens.

3. Turn off power before replacing fuses.

4. Locate and correct the cause of a blown fuse or tripped circuit breaker before replacing fuse or resetting breaker.

5. Experimental circuits and wiring practice boards should be fused properly.

6. Make wiring changes only with power OFF.

7. Make sure wire size and insulation is appropriate for the job.

8. Disconnect or unplug appliances and equipment before attempting repairs.

9. Make it a habit to inspect cords, plugs, etc.

10. Make sure portable electrical devices are properly grounded.

11. Never attempt to use a piece of electrical equipment known to be faulty.

12. Chassis of AC-DC radios should be kept clear of any grounded conductors. Use an isolation transformer if available, otherwise determine polarity and reverse plug if necessary.

13. Make sure capacitors are discharged before touching. Experimental power supplies should incorporate "bleeder" resistors.

14. Disconnect power cord before touching anything behind front panel of transmitter.

15. Remove headphones before working on equipment.

16. Make it a habit to keep one hand in your pocket or behind your back when using a test probe.

17. Wear gloves and a face shield when handling cathode-ray tubes. Old CRT's should be smashed in a large steel barrel by dropping a heavy metal rod through a hole in the top of the barrel. Never have CRT's setting around as "curiosities."

18. Metal jewelry, watches, rings, chains, etc. should not be worn when working on electrical equipment.

19. Always wear safety glasses when soldering.

20. Follow instructions when handling and charging storage batteries. Wear safety glasses.

21. Keep sparks and flame away from storage batteries, especially when being charged.

the organization or goals of the various sub-divisions within the organization.	
j. Responsibility - it is the obligation of the individual to perform the duties assigned to him to the best of his abilities. In another sense, a responsibility may be regarded as the same as duty.	
The following terminology for identification of levels of groupings of activity within the organization is suggested. These terms are commonly used by governmental employees and can be used to advantage in a discussion of governmental organization or functions. (References to parts of existing organizations must, of course, make use of the terms officially adopted to designate them.)	

20395

REFERENCES

Name of Part of Organization	Identification of Level	Example
Department	The basic functional part of the organization in its entirety.	Department of Public Safety
Division	The major, formal, functional parts of a department.	Motor Vehicle Inspection Division
Bureau	The principal, established, functional parts of a division.	Field Operations Staff Operations Services
District	Geographic sub-division of the organization. The principal areas under one command or control.	Western District District #1 Troop A
Section	Any recognized permanent or semi-permanent specialization in a bureau.	Special Investigations
Unit	Further specialization, often temporary, within a section.	Undercover Investigations
Detail	Temporary assignment or project in relation to a specific matter.	Spotcheck Detail

Section, Unit, or Detail may temporarily apply directly under Department or Division.

4. When preparing an organizational arrangement for the motor vehicle inspection program, specialization, span of control, centralization, de-centralization, line and staff functions are matters which require consideration by the administrator. Once an organization has been finalyzed and implemented, these same matters should always be under consideration by the administrator so that the organizational structure will be a "living" thing and will be able to adjust to the needs of the times. Too often this is not the case. a. Specialization must be considered so that the specialized efforts can be integrated toward organizational goals. As it concerns the operational levels of a vehicle inspection program, specialization can be graphically illustrated at least three different ways depending on decisions made as to the classes of inspection to be included in the program and the degree of supervision to be included within each class.

b. Span-of-Control refers to the theoretical or practical limit to the number of units or subordinate personnel who can be effectively supervised or controlled by one individual. Conversely, it is the number of units or subordinate personnel reporting to a single person. In programs where inspections are conducted in state-owned stations, span-of-control will mainly be concerned with personnel. In the state-appointed programs the theory of span-of-control deals with personnel within the governmental agency administering the program and must also take into consideration the number of inspection stations which will be assigned to a Station Supervisor. Factors that should be taken into consideration concerning this aspect of organization are competency and geographical location (dispersion) of subordinates and supervisors, personal authority of subordinates to make decisions, type and amount of	

20399

	REFERENCES
work being performed, relationships among the management group, and acceptance of the vehicle inspection program by inspection station personnel and the public.	
c. <u>Centralization and De-centralization</u> must be considered in vehicle inspection programs due to the geographical dispersion of the involved activities. The administrator must assign personnel and activities on the basis of need in relation to time and area to effectively equalize workloads and responsibilities. Factors entering into this are geographical dispersion, size and complexity of the organization, ability of superiors and subordinates, management philosophy of the administrator, economics, and lines of communication. The degree of decentralization will differ among states, but the administrator must be made aware that as he decentralizes the need of controls is increased in	

20400

	REFERENCES
order to maintain consistency of/with policy and technological competence in order that objectives of the program may be obtained.	
d. Line refers to those functions and activities which are basically concerned with fulfillment of the primary responsibility of the vehicle inspection program, the translating of plans and policies into action in the field. In state-owned programs it would be generally characterized by direct contact with the public. In state-appointed operations it still is concerned with direct contact with the public. The public in this case including inspection station personnel. In determining the background and training desirable in line personnel, the administrator of the vehicle inspection program must first decide upon the functions they are to perform. A check of existing programs shows that some favor line personnel to	Ref. #1 - par. 2.9.2.

	REFERENCES
have mechanical training and others favor law enforcement experience.	
e. Staff refers to those non-line functions and activities which serve the purpose of developing personnel and the agency to most effectively meet their responsibilities. The functions generally include those activities which provide technical, special, and other supportive activities necessary for the organization to accomplish its mission. When deciding upon an organizational structure for the vehicle inspection program, the administrator must first decide upon the staff assistance which will be required by the line operation and which of this assistance can be obtained form outside the agency. He then needs to place the internal staff functions into logical groupings for the purpose of including them in his organizational structure.	

	REFERENCES
5. The Insurance Institute for Highway Safety, in its Management Manual for Motor Vehicle Inspection, suggests organizational structures for both state-appointed and state-operated systems which the National Highway Safety Bureau considered sufficiently appropriate to include as examples in the Highway Safety Program Manual, Volume I - Periodic Motor Vehicle Inspection. These charts serve the purpose of graphically representing the arrangement and inter-relationships of the functions and sub-divisions of a motor vehicle inspection program, and are included in this syllabus so that the instructor can have a basis on which to formulate his presentation. (It is emphasized that these charts are not meant to represent the optimum organizational arrangement for a vehicle inspection system, but are included here so that the lecturer can have a starting point for developing, with the class, an organization chart that will meet the needs of a motor vehicle inspection program.) C. Administrative and Managerial Responsibilities 1. The task of guiding, leading and controlling the cooperative functions of a vehicle inspection program towards a common goal involves many processes and areas of activity which are usually only alluded to in an organizational chart. The degree of success that a program attains, however, will often depend on the ability of the administrator to integrate these processes and activities into the framework of his organization. It is axiomatic that three basic administrative processes vital to the achievement of the goals of an organization are: (1) planning the operation; (2) implementing the plan; and (3) controlling the results. This syllabus is built on that premise and includes pertinent blocks of instruction. 2. It is easy, however, to become entwined with administrative terminology. When discussing organizational charts it must be remembered that the chart can only	

20405

	REFERENCES
"make provisions for" but cannot guarantee anything. The chart itself can, and should, be used to assure provisions for:	Ref. #2 - p. 20
a. Allocation of responsibility.	
b. Equitable distribution of workloads.	
c. Clear lines of authority.	
d. Proper delegation of authority.	
e. Reasonable spans of control.	
f. Unity of command.	
g. Coordination of effort.	
h. Administrative control.	
But the "chart" is just that -- a "chart" -- unless the right men are found for the right job. When discussing organization, this refers to men who have an understanding of various functional elements of work that go into making a "chart" come to life and assist the organization it represents to accomplish its mission. The work that the administrators and managers must be able to do can be referred to as POSDCORB, which is a made	Ref. #3 - p. 97

20406

	REFERENCES
up word which has been used since 1937, but which is still meaningful today when talking about organizational structures. It stands for: a. Planning - working out in broad outline the things that need to be done and the methods for doing them to accomplish the purpose set for the enterprise. b. Organizing - the formal structure of authority through which work subdivisions are arranged, defined and coordinated for the defined objective. c. Staffing - the whole personnel function. d. Directing - the continuous task of making decisions and embodying them in orders and instructions. e. Co-ordinating - the all important duty of interrelating the various parts of the work. f. Reporting - keeping everyone informed.	Ref. #3 - p. 13

20407

	REFERENCES
g. Budgeting - with all that goes with budgeting in the form of fiscal planning, accounting and control.	
D. Summary	
1. In order for the periodic motor vehicle inspection program to achieve its mission it must operate within a philosophy which exists to assist in the accomplishment of objectives. This philosophy needs to recognize the part that organization plays in achieving goals by taking into consideration areas of specialization, levels of command, span of control, grouping of activities, delegation of authority and centralization. The leadership of a vehicle inspection program should be aware of the importance of properly organizing the various functions involved into an organizational structure which remains sufficiently simple and flexible to facilitate the accomplishment of objectives while embodying a teamwork approach to other agencies who have as their goal the motoring safety of the public.

SUBJECT: SELECTION AND TRAINING OF FIELD SUPERVISORS

HOURS: 3

OBJECTIVES: To develop an understanding of the qualities and attributes desirable in supervisors; to create an understanding of the problems involved in the selection and training of supervisors, and suggested ways and means of solving them.

METHODS OF INSTRUCTION: The primary method of instruction for this unit is lecture.

References 1 and 2 contain much information which the lecturer can utilize in developing the supervision aspect of his presentation. References 3 through 6 should be referred to when connecting supervision to the motor vehicle inspection program.

20410

INSTRUCTOR'S GUIDE

(SELECTION AND TRAINING OF SUPERVISORS)

I. INTRODUCTION

A. Instruction should provide the student with an understanding of the function and importance of supervision by examining the relationships which underlie the supervisor's duties and responsibilities. The student should be made aware of the importance of selecting and training supervisors with the desirable qualities and attributes.

The important role of the Field Supervisor in a successful vehicle inspection program should be emphasized. The student should understand that violations of the intent of an inspection program can largely be eliminated if Field Supervisors properly fulfill their function.

20411

	REFERENCES
II. PRESENTATION	
A. Needs of Field Supervision	
1. A fundamental requirement for making periodic motor vehicle inspection accomplish its purpose of enhancing highway safety is controlling improprieties of inspection personnel. Close supervision of inspection stations is necessary to maintain high quality inspections and to create public confidence in the program. While this is important when the stations are owned and operated by the regulatory authority, it is even more important when they are appointed and licensed by them.	Ref. #3 - P. 23 Ref. #4 - p. 7 Ref. #5 - p. 7 Ref. #6 - p. 4 - Chap. IV
2. In order to allow a constant exchange of information about the motor vehicle inspection program and to provide for close observation and evaluation of its effectiveness, in-the-field supervision of the Station Supervisors should be a primary function of the Field Supervisors. The Field Supervisor should periodically make unannounced visits to inspection stations and personal reinspection of some recently inspected vehicles.	Ref. #3 - p. 26

20412

	REFERENCES
a. This results in better evaluation of the station supervisors and a more effective motor vehicle inspection program.	
3. It is unfortunate but true that field supervisors who have many responsibilities in addition to motor vehicle inspection do not always give their inspection responsibilities the priority they deserve. This emphasizes the need of a proper selection and training program.	
B. What is a Supervisor?	
1. When attempting to define "supervision" it is helpful to go to the Latin origin of the word: "super" meaning over and "vision" meaning sight or seeing. In management, then, supervision indicates someone who is watching from above, but goes further and indicates that this someone is looking down with authority. This is the heart of supervision - the presence of someone up above to look to for assistance and guidance - and the realization that this same someone, the supervisor, is watching to	Ref. #1 - p. 3

20413

	REFERENCES
make sure assignments are carried out properly. a. A supervisor is anyone whose working relationship is such that he is directly responsible for the assignment, supervision and/or evaluation of the performance of at least one other employee. This emphasizes that the function of supervision must operate at all levels within the organization. 2. The success of an organization often depends on the ability of its supervisors, for it is to his supervisor that an employee looks for most guidance in determining the detailed requirements of his job; the supervisor is the key figure in developing competence in the employee, and studies have shown that the satisfaction an employee derives from his work depends more on the kind of leadership and motivation provided by his supervisor than on such material values as wages and hours.	

APPENDIX

	REFERENCES
C. Importance of Planning in the Selection and Training of Supervisors 1. When speaking of the selection and training of supervisors it is important not to separate these into two distinct functions, but to consider them as one process which is continuous. Training of potential supervisors should always be going on even under circumstances of which the person being trained is not aware. For example, giving assignments which call for decision-making is a part of the training process which allows observation of potential supervisory talent. Selection occurs at intervals during this training process, and what the "student" has been undergoing in an informal situation becomes a formal program. By having selection and training be interdependent and interwoven functions, going on all the time, supervisory ability which otherwise may have gone unnoticed may become apparent and/or training needs may be shown by the weaknesses in the man after he is supervising.	

20415

	REFERENCES
2. Planning increases the awareness of the need for supervisory training, for it recognizes that the efficiency of an operation is dependent on the quality of supervision. When the planning phase takes an objective look at the supervision program it should recognize that the basis for appointment to a supervisory position should be the potential supervisory ability of the individual under consideration, and not just such things as: a. Satisfactory performance of a lower job. b. Seniority - reward for length of service. c. Politics - pressure groups. d. Tested knowledge of non-supervisory areas - technical know-how. 3. A planned program should provide a reservoir of potential supervisors by providing a system for obtaining, recording, filing and using information concerning them. This recognizes the need for the	

20416

	REFERENCES
selection and training process to start long in advance of the actual appointment to a supervisory job and emphasizes the fact that low level supervisors are recognized as the source from which future administrative personnel are selected.	
D. Basic Elements of the Selection Program	
1. A basic philosophy in personnel management is that each employee should be utilized in a manner which will make the greatest contribution to the total enterprise. It may be difficult to achieve this to a degree approaching perfection, but within the realm of practicality and within the authority of the department head to assign and transfer, this philosophy must be considered. To increase the probability of success of a motor vehicle inspection program while providing the necessary guidance to the professional growth of subordinates, one must base the selection of inspection supervisors on more important considerations and factors than whim, opportunity and convenience. Factors which should have bearing on the selection	

20417

	REFERENCES
of the supervisor are: a. Personal interests and motivation. b. Special aptitudes, with or without developed skills. c. Experience and training - general background of work. d. General skills or proficiency, as demonstrated in service. e. Special skills or proficiency or any special qualifications in any way related to his possible use. f. Ultimate potential, as well as this can be appraised. g. Need for and importance of the service the individual can contribute. (1) No one factor is mentioned as necessarily more important than any other, since the special circumstance of <u>this</u> assignment in <u>this</u> organization should determine the importance of a factor.	

20418

	REFERENCES
2. To assist him in selecting supervisors the administrator should give consideration to: a. Merit rating which covers areas important to the level of supervision. b. Intelligence tests which measure the ability of the supervisor to think and make decisions which his level of supervision will require. c. Job knowledge tests which will indicate to what degree the supervisor knows the tasks which he will be supervising. d. Personality tests which should indicate to what degree the supervisor will be able to lead and motivate. e. Interviews by qualified superior officers who have displayed the ability to fill the position for which the supervisor is being chosen. f. Medical tests to ensure the continued employment of the supervisor so that the investment in him can be recouped.	

	REFERENCES
3. In order to assign the appropriate amount of weight to the factors mentioned above, and to decide on appropriate selection procedures to employ, the administration of an organization should first study the job to be filled by the supervisor. After analyzing the job content and requirements, the duties should be put in writing. This is also true of the responsibilities and relationships of this supervisory position. This should make it easier to determine the qualifications needed for a person to successfully fill the position and the methods to use to uncover those who may have those qualifications.	
E. Basic Elements of the Training Program	
1. In many organizations training is "something we do" - an activity, or a process - rather than a program designed and used to solve problems and fill needs. Like vitamins we buy without a prescription, most training is "good." But training must be more than just good; it must be based on the job requirement of the trainee; it must be built around the identified problems and needs of	

	REFERENCES
the trainee; and it must, in fact, produce some change in attitude, in understanding, or in performance. This is particularly important when the training is aimed at taking a person out of the operational level of an organization and inserting him into the management stream. The nature and purposes of training programs vary a great deal, but for the purposes of this presentation they can be grouped into three categories:	Ref. #2 - p. 268
a. Developing job knowledge and skills. This becomes particularly important within the motor vehicle inspection program, for in addition to the knowledge necessary for the supervisor to be effective to the over-all purpose of his organization, he will need specific knowledge and skills of a mechanical nature. Skills, as used here, covers manual skills necessary to the motor vehicle inspection program and interpersonal relations skills necessary to supervise people.	

	REFERENCES
b. Transmitting Information. This training program is directed toward transmitting general information about the organization, its purposes, policies, rules, etc.	
c. Modifying Attitudes. This program is of particular importance to a new level of supervisors. Its intent is to develop more favorable attitudes toward and appreciation for the position of supervisor, and to increase the supervisor's ability to motivate subordinates to perform in the manner desired.	
It is readily apparent that all three types of programs need to be meshed into one when deciding on a training program for supervisors.	
2. Supervisory training must have the endorsement and participation of top management of the organization. Management must set the climate for training effectiveness through its insistence that procedures and knowledge taught in a training course be	

	REFERENCES
utilized. With this in mind, supervisory training must be designed to meet the needs of the organization concerned. Guidance from other organizations can be helpful, but for the program to be more meaningful to the students, management policy, philosophy, and organization of the supervisor's own department must be incorporated into the program. Supervisory training should include, and probably should start with, top management. This can be achieved through their participation in the planning and defining of the policies, philosphy and contents of the training program. This should not eliminate other levels from consideration when the training program is being developed. The supervisors themselves should be involved in defining their problems and approaches to the solutions of these problems.	
3. Once the objectives of a supervisory training program have been decided upon, it is necessary to determine what method of training is best suited to accomplish the objective. Some techniques might be in-	

20423

	REFERENCES
dividual coaching, group conferences, classroom lectures, rotating assignments, case studies, on-the-job and/or off-the-job training. To the maximum extent possible, subordinate supervisors should be trained by their supervisors with the advise and assistance of staff personnel as necessary. This does not mean that the supervisor would do all the teaching, but rather that his knowledge would be used to the fullest with some teaching required. Supervisory training should be dynamic in character. That is, subject to adaptation and progressive improvement. As changes in supervisory techniques are suggested they should be included in the training program. As changes in periodic motor vehicle inspection standards and requirements come about the supervisor should be notified and the changes should be made clear to him so that he, in turn, can so instruct his subordinates, the station supervisors. Performance of supervisors and potential supervisors in the training situation should be an important consideration in making selections for	

NATIONAL STANDARD SCHOOL SHOP SAFETY INSPECTION CHECK LIST

Prepared by the Joint Safety Committee of the
AMERICAN VOCATIONAL ASSOCIATION — NATIONAL SAFETY COUNCIL

_____ Date _____

_____

INTRODUCTION

A safe environment is an essential part of the school shop safety education program. The safe environment will exist only if hazards are discovered and corrected through *regular* and *frequent* inspections by school personnel—administrators, teachers and students. Safety inspections are to determine if everything is satisfactory.

Inspections may be made at the request of the board of education, the school administration or upon the initiative of the teacher. Some communities have drawn upon the cooperative service of professional safety engineers, inspectors of state labor departments, insurance companies and local safety councils to supplement and confirm inspections by school personnel.

The National Standard School Shop Safety Inspection Check List, recommended by the President's Conference on Industrial Safety is an objective inspection procedure for the school shop.

DIRECTIONS

WHO INSPECTS?

This will depend upon local policies. It is recommended, however, that shop teachers, and students—the student safety engineer and/or student safety committee—participate in making regular inspections. This not only tends to share responsibility but stimulates a broader interest in the maintenance of a safe school shop.

WHEN TO INSPECT?

As a minimum, a safety inspection should be made at the beginning of every school term or semester. More frequent inspections may be advisable.

HOW TO INSPECT?

Inspections should be well planned in advance.

Inspections should be systematic and thorough. No location that may contain a hazard should be overlooked.

Inspection reports should be clear and concise, but with sufficient explanation to make each recommendation for improvement understandable.

FOLLOW-UP

The current report should be compared with previous records to determine progress. The report should be studied in terms of the accident situation so that special attention can be given to those conditions and locations which are accident producers.

Each unsafe condition should be corrected as soon as possible in accordance with accepted local procedures.

A definite policy should be established in regard to taking materials and equipment out of service because of unsafe conditions.

The inspection report can be used to advantage as the subject for staff and class discussion.

CHECKING PROCEDURE

Draw a circle around the appropriate letter, using the following letter scheme:

S — Satisfactory (needs no attention)
A — Acceptable (needs some attention)
U — Unsatisfactory (needs immediate attention)

Recommendations should be made in all cases where a "U" is circled. Space is provided at the end of the form for such comments. Designate the items covered by the recommendations, using the code number applicable (as B-2).

In most categories, space is provided for listing of standards, requirements or regulations which have local application only.

A. GENERAL PHYSICAL CONDITION

1. Machines, benches, and other equipment are arranged so as to conform to good safety practices ..... S A U
2. Condition of stairways ..... S A U
3. Condition of aisles ..... S A U
4. Condition of floors ..... S A U
5. Condition of walls, windows, and ceiling ..... S A U
6. Illumination is safe, sufficient, and well placed ..... S A U

	REFERENCES
higher supervisory positions. This should be made clear to the student-supervisor so that there will be no doubt in his mind that the intent of the training program is to have a more qualified supervisory level of personnel. It must be recognized by management, training personnel and the student-supervisors that training should not be expected to compensate for poor selection. Training is a further continuation of the selection process and if it is found that a person has been selected to be a supervisor but he cannot comprehend the new requirements of his position, or cannot perform to the level required of supervisors of his position, procedures should be present which provide for this to be called to the attention of the appointing authority so that corrective measures can be taken. Mediocrity breeds mediocrity. If personnel are to remain effective and if the motor vehicle inspection program is to accomplish its goals, field supervisors must be able to supervise people - and to effectively control the function to which their subordinates are assigned.	

20425

	REFERENCES
F. Summary 1. In order for a periodic motor vehicle inspection program to meet the planned for success it is necessary to have knowledgeable, dedicated station supervisors monitoring the program in the field. To ensure the effectiveness of a level of command, the next higher level of supervisors must be properly trained in the techniques of supervision and the program being monitored. The purpose behind properly selecting and training field supervisors is to have levels of supervisors who are able to motivate subordinates to do their best for the organization they represent, both in furthering the image of the organization and in functioning in the manner for which the organization is in existence.

SUBJECT: FIELD SUPERVISION AND ENFORCEMENT

HOURS: 4

OBJECTIVE: To develop an understanding of the role of field supervision and enforcement in a motor vehicle inspection program with emphasis on management's responsibility to the vehicle owner and the inspection station.

METHODS OF INSTRUCTION: The primary method of instruction for this unit is lecture. Extensive use should be made of training aids and handout material when discussing the various types of forms used during initial application, inspection and enforcement.

In addition to the noted reference material, three states with programs which the lecturer could refer to when preparing for his presentation are:

Georgia: Department of Public Safety
Motor Vehicle Inspection Division
PO Box 1456
Atlanta, Ga. 30301

Texas: Texas Department of Public Safety
5805 N. Lamar Blvd.
Box 4087, North Austin Station
Austin, Texas 78751

Virginia: Commonwealth of Virginia
Department of State Police
PO Box 1299
Richmond, Virginia 23210

INSTRUCTOR'S GUIDE

(FIELD SUPERVISION AND ENFORCEMENT)

I. INTRODUCTION

A. Instruction should provide the student with an understanding of the function and importance of field supervision and enforcement in the motor vehicle inspection program. The student should be made aware that inspection stations and mechanics, whether state employed or state appointed, must be under close and positive supervision by the state. It should be emphasized to the student that enforcement of laws, rules and regulations governing the operation of the motor vehicle inspection program is necessary to ensure compliance with the program objectives and acceptance of these objectives by the motoring public.

20429

	REFERENCES
II. PRESENTATION	
A. The Need of Field Supervision and Enforcement.	
1. An aim of motor vehicle inspection programs is for every vehicle owner to have his vehicle voluntarily inspected and repaired in the interest of safety because he believes that everyone with whom he comes in contact on the public streets and highways has done likewise. As this aim comes closer to reality the number of collisions caused by vehicle defects should be correspondingly reduced. In order to achieve this aim, however, it is necessary for administrators to include in their inspection programs enforcement procedures which will ensure that defective vehicles are repaired, but only when justified, and that inspection stations are accurately and honestly complying with prescribed standards and procedures. Conversely, the absence of sound enforcement procedures can result in a breakdown of the inspection program and the loss of the public confidence and support which is necessary for success.	Ref. #5 - p. 37 Ref. #1 - p. 7

	REFERENCES
2. Field supervision and enforcement, in the present context, refers to those functions necessary to ensure an "honest" operation of the motor vehicle inspection program.	
B. Investigation of Applicants.	
1. A segment of the field supervision and enforcement aspects of inspection programs has to do with the investigation of applicants who desire to have their stations certified as inspection facilities. It is axiomatic that state owned and operated inspection facilities would meet the requirements of the program but in those states where the inspection stations are not owned by the state but are licensed by them, basic requirements for approval and licensing should be imposed. Then, when an application is received requesting certification of an inspection station, a part of the qualifying process should be a field investigation of the applicant and his facility to ascertain if the basic requirements are met.	Ref. #1 - p. 27
2. Success of an inspection program depends	Ref. #1 - p. 29

	REFERENCES
heavily upon the caliber and adequacy of the people who inspect the vehicles. Basic requirements which mechanic-inspectors must meet should be set forth and, as with the stations, when an application for certification is received a part of the qualification process should be a field investigation of the applicant to determine if he meets the basic requirements. This procedure should be adhered to whether or not the inspection program is state-owned or state-licensed.	
C. Supervision of Inspection Stations and Mechanics.	
1. Both state-owned and state-operated and state-licensed stations must be regularly inspected to ensure that policies and procedures are followed. As a general rule, it would be desirable to have sufficient station supervisors to allow each station to be visited at least monthly on a regular basis. In order for the inspection program to accomplish its purpose the station supervisor should be allowed sufficient time to properly inspect the facility, its records and employees, and should have a form setting forth the items to be checked with space to note the results.	Ref. #3 - par. 2.9.1.

20432

	REFERENCES
The inspection form should be in sufficient copies to give the station management a copy and to have copies placed in the administering agency's files. In addition, when the station supervisor is filling the role of investigator, he should also visit the stations to help the station personnel perform more effectively by clarifying the legislative and administrative intent of rules and regulations, and to provide a channel of communication for feedback from the public and station personnel to the program administrator.	
2. A program of undercover spot-checks should also be a part of field supervision and enforcement. This should be done by having agency personnel who are unknown to a particular geographic area drive vehicles with known defects in for inspection. The actions of the inspector in these situations should be governed by the reason for this spot-check, i.e., routine, because of complaints against the station; because of suspicions that the station is "winking" at	

B. HOUSEKEEPING

1. General appearance as to orderliness..... S A U

	REFERENCES
inspection program is an on-going process.	
D. Field Enforcement	
1. By field supervision and enforcement we also mean efforts aimed at assuring that the public comply with the periodic motor vehicle inspection laws, rules and regulations. To facilitate this an easy means of identifying those vehicles which have not been currently inspected needs to be developed by the program administrator. In this regard the administer should not be governed only by tradition or by what others are doing. He should solicit ideas from line personnel who enforce the inspection statute as to the easiest means of identifying non-inspected vehicles.	Ref. #4 - p. 15
a. For example, while it is the usual practice to place inspection stickers on the auto windshield, it may, for enforcement purposes, serve a better purpose on the rear window.	

20435

	REFERENCES
2. Agencies which have the authority to enforce the motor vehicle inspection requirements must then cooperate to have a united front to confront violators with this aspect of the motor vehicle laws. No one agency can accomplish this alone -- and cooperation among the many police agencies in a state should be the rule rather than the exception. Cooperation in this function is not a one-way street. The agency in charge of the motor vehicle inspection program should keep other enforcement agencies informed as to the aims and accomplishments of the program and changes which are made within it. These other agencies should comply to their utmost with the valid requests of the administrator of the motor vehicle inspection program.	Ref. #2 - p. 10
E. Summary	
1. The success of periodic motor vehicle inspection programs depends upon the systematic enforcement of safety equipment requirements uniformly applied to all.	Ref. #1 - p. 2

20436

	REFERENCES
To accomplish this there must be continuous, impartial field supervision of inspection stations and personnel, and sustained enforcement action taken against those who refuse to comply with regulations.	

20437

SUBJECT: RECORDS AND INFORMATION

HOURS: 8

OBJECTIVES: To improve the student's understanding of the need for complete and accurate records within the periodic motor vehicle inspection program. To make the student aware of the types of information on which a successful program can be evaluated and the procedure for receiving and processing this information into meaningful data. To develop an understanding in the student of the need for a well planned management information system.

METHODS OF INSTRUCTION: The primary method of instruction for this unit is lecture, supplemented by classroom project discussions. Maximum use should be made of forms and reports now in use within the students' jurisdictions.

INSTRUCTOR'S GUIDE

(RECORDS AND INFORMATION)

I. INTRODUCTION

A. Instruction should identify the importance of the records function and should familiarize the student with the information which a vehicle inspection program should produce in order for management to fulfill its responsibilities to the organization and to the public that organization serves.

It should be emphasized to the student that periodic motor vehicle inspection data does not exist merely for the gathering agency, but is part of a total information gathering system which must be integrated if the aims of traffic safety and vehicle inspection programs are to be met.

The student should be shown the need for his functional input to the total management information system, and how management benefits from effective inputs from his level.

20440

	REFERENCES
II. PRESENTATION	
A. The Need for Records and Information	
1. The successful vehicle inspection organization accomplishes its mission by moving forward within well-developed programs. These programs, to be effective, must be created and continued on the basis of factual information. Appropriate records, properly maintained and carefully analyzed, are the means for making this factual information available to the program administrator. By records we mean all the documentary materials, regardless of physical form or content, which are produced in connection with the vehicle inspection program and filed to be available for reference as the need arises. Information is the content of those records.	Ref. #4 - p. 1
2. Reliable records data should serve many valuable purposes. They should be the official memory of the agency and should assist it in accounting upward and outward for its activities and for the justification of its programs. They should provide	Ref. #5 - par. 5.1.1.

	REFERENCES
information to other agencies which share responsibilities in vehicle safety. They should fill the void that now exists as to documentary proof of the effectiveness of vehicle inspection in highway traffic safety.	Ref. #1 - p. 5
3. The concept of management's use of data recognizes that, essentially, records-keeping and information processing are performed for the purpose of providing management with information to plan and control agency activity. In order to efficiently use information from the records system the various levels of management within the vehicle inspection organization should be identified and their decision-making responsibilities clearly understood. Then the managers at the various levels can ask for the data necessary on which to base decisions.	
a. To a large extent the primary responsibility of the supervisory level of management is the motivation of subordinates. Planning and organizing activities at this level largely	

	REFERENCES
concern the effective utilization of subordinate personnel on a day-to-day, or at least short-range basis. Informational needs of this level usually correspond to geographical areas of assignment of first line supervisors and often are restricted to the goals of sub-units within the vehicle inspection organization.	
b. Top and middle management's responsibility, on the other hand, is not as much in the area of motivation of subordinates as it is in the development of long-range plans, evaluating progress towards organizational goals, and coordinating efforts within the inspection agency and with other organizations. This level's informational needs encompass the whole organization and the total highway safety program as pertains to vehicles.	
4. The National Highway Safety Bureau has focused attention on sixteen program areas to be coordinated into a unified attack on

traffic accident causes. These areas have been reduced to Highway Safety Program Standards, and it is expected that additions will be made to them. Each of these Standards is supplemented by a Highway Safety Program Manual. The Manual dealing with Traffic Records emphasizes that agencies which operate in any of the Standard areas, of which one deals with periodic motor vehicle inspection, can expect many federal, state, local and private organizations to be requesting information about their activities. Realizing that vehicle inspection data is part of an overall information system, the program administrator must adopt techniques and practices which further the aims of the total program while enhancing his own operations.	Ref. #6 - Chap. IV
B. A Management Information System	
1. The Federal Bureau of the Budget has defined management information as "That information required by managers to evaluate and control their organization's progress and to substantiate their formulation of judgments for	

	REFERENCES
executing their decision-making and management responsibilities." The Bureau defines system as "A set of interdependent elements arranged to interact harmoniously and effectively to serve one or more specific purposes. The elements include (1) people and organizations; (2) software, methods, processes, procedures, techniques; (3) hardware equipment and facilities; and (4) an integrated and regulating mechanism for effective operation." Therefore, it can be said that a management information system is the people, equipment, and techniques which secure, file and retrieve information which managers need to plan, operate and evaluate activities. Viewed functionally, management information systems are three distinct but highly related management activities. Planning - Operations - Evaluations - linked by a constant flow of information. All during these activities the three functions are continually supported by reports and records derived from a data base. a. For the most part this data base consists of the information normally used	

	REFERENCES
or accumulated in the organization's operations. It should also include related data from other agencies, i.e., number of registered vehicles, census information which may have a bearing on programs, accident causes, police enforcement pertaining to vehicle defects, etc.	
b. This is important when measuring the impact of particular programs, or when identifying specific problem areas toward which new programs need to be directed.	
An overview of a management information system can be as follows:	Ref. #3 - p. 4

20446

	REFERENCES

C. Scope of This Presentation

1. Vehicle inspection records connect with and overlap records relating to other internal programs and activities which have a bearing on the agency's mission.

This block of instruction will be concerned with only those records which directly refer to the inspection of vehicles, the people doing the inspection, and the establishments

	REFERENCES
where the inspections are conducted. (It is difficult, in a syllabus of this nature, to suggest one set of informational requirements that will satisfy the needs of all motor vehicle inspection programs. So that the lecturer may extract that information which is meaningful to his particular group, inputs and outputs will be suggested later in this presentation. They consist of data required or suggested by the National Highway Safety Bureau, guides published by agencies like the American Association of Motor Vehicle Administrators, and common sense.)	
D. Outputs of the Record System	
1. A problem that sometimes arises when record systems are being designed or updated is that equipment and procedures are decided upon only on the basis of information that is to be placed into the system. As a result, it is not unusual for files to become filled with records that are never used, and for expensive electronic equipment to never reach its potential for use.	

20448

	REFERENCES
To overcome this pitfall of economy and efficiency, the administrator should decide what the records system is expected to produce before he decides on methods or equipment. Generally speaking, outputs of a motor vehicle inspection records system are of five kinds: a. Facts relating to a specific past event. The inspection of a vehicle or the certifying of an establishment to be a vehicle inspection station are examples of this. b. Descriptions of a specific inspection station, mechanic-inspector, or vehicle; for example, the class of vehicles a particular station or mechanic is certified to inspect, the age and odometer reading of a vehicle at the time of inspection. The description may be a single item, or it may include all the information in the record. c. Periodical summaries of events during a period and in an area. This output totals data by categories for groups of	

	REFERENCES
events, such as vehicles inspected and passed, or vehicles inspected and failed.	
d. Periodical inventories of characteristics of individual stations, inspectors, and vehicles. This totals data by categories. Such inventories may include rejected vehicles by make and model, mechanic-inspectors by scope of certification, and stations by classes of vehicles authorized to inspect.	
e. Special summaries and inventories which may be required by authorities from time to time. These may include data from other sources such as accident records and vehicle recall notices. Special reports are usually for research and exploratory purposes. The vehicle inspection administrator should anticipate these requests, for it can be expected that the effect motor vehicle inspection has on vehicle involvement in crashes will be a matter of interest in highway safety for a long time.	

20450

	REFERENCES
2. In addition to taking in, digesting and giving out data as described in preceding paragraphs, the system should also provide for the following special services: a. Comparisons between various output reports and data obtained from other sources. (1) Rates are a form of such comparisons. Examples would be the number of vehicles inspected per the number of vehicles registered in a state; citations for uninspected vehicles per number of uninspected vehicles; number of vehicles found with serious defects per number of vehicles inspected. (2) Trends are changes in numbers or rates from time period to time period. Trends may include comparisons of accident experience before and after a change in the vehicle inspection program. Trends of the numbers of inspections conducted may be used as a	

	REFERENCES
basis for projecting future facility and personnel needs.	
(3) Relative experience of classes of vehicles within the requirements of the vehicle inspection program.	
b. "Sounding an alarm" to call attention to a condition which needs correction. This is the records aspect of management by exception which should come into play when some standard of guide is not matched, when trends become unusual, and/or when conditions or performances deviate considerably from the average or mean. Management by exception will be discussed more fully later in this presentation.	
c. Routine operations which enhance the effectiveness of the vehicle inspection program and which the records system can do economically and efficiently. Examples of this would be (1) notification to people and establishments to renew and update	

	REFERENCES
their certification and (2) follow-up on vehicles which were rejected to make sure they have been resubmitted for another inspection within the time specified.	
3. The justification of vehicle inspection records is support for vehicle inspection programs. It is important that records system outputs and services match programs. Inadequate records will hamper development of programs; superfluous records will waste money and effort. It is necessary, therefore, for records system personnel to work closely with administrators of the programs in planning the reports managers want, especially for decision-making. As a basis for reaching agreement as to what outputs will be included, each output and each specific information item considered for that output should be considered according to whether it is (1) necessary; (2) useful, but not necessary; (3) nice or impressive, but not especially useful; and (4) something somebody imagined ought to be included, but might never be used. All of number 1 should

be produced; none of number 4 should be. Whether 2 or 3 are produced will depend on the availability of resources and the relative importance of different programs.	
4. Exhibits 1 through 14 of this unit are output reports which the Traffic Institute has suggested should be produced in connection with a vehicle inspection program. For each output, three elements are listed: a. Title (what the report concerns). b. Identifying data (time, area, group of people, group of vehicles). c. Information reported or summarized. The sheets are designed so that they can be used by the instructor for project assignments or classroom participation. In this regard the second section of each sheet leaves space for the class to evaluate the need for the particular output report, whether the existing report is sufficient and, if not, what changes are required. There is also space for the class to make an estimate as to the number of individual

Requirements

A: Form design or form standardization

B: Data collection improvements

C: Data processing and storage

D: Funds, management decisions

The instructor should also consider having the class assign priorities of importance to the listed outputs. Codes which could be used for this are:

	REFERENCES
Priority a. Immediate attention required. This information is necessary for a successful program. b. Prompt attention suggested. This information is important to the program and is economically and operationally sensible to produce now. c. Future attention required. Other recommendations need adoption before this information can be accommodated. d. Future attention suggested. This information is part of a complete program but unnecessary for a successful one. E. Inputs to the Records System 1. A records system can produce output records only to the extent that input data have been provided. If unavailable information is repeatedly requested from the system, program managers should arrange to provide the necessary input -- if the records system can handle it.	

20456

	REFERENCES
2. A unit of input is not a piece of paper, but a piece of information. Usually the input is on a paper arranged as a form for convenience. A single paper form may include many inputs. For example, a report from an inspection station may show, one to a line, the results of inspecting 20 vehicles; this is not one but twenty unit inputs, each relating to a different inspection. Or a single form may include a mechanic's application for certification as an inspector as one input and the investigator's approval or disapproval as another from a separate source. These two could be on separate forms, or they could be at different locations on the same sheet. There is advantage in making each form serve as many purposes as possible. It reduces the number of forms and it makes transcribing data from them a more standardized process.	
3. It once again must be emphasized that periodic motor vehicle inspection is part of a total highway safety program and that the information gathered within the inspection	

	REFERENCES
program must be made available to other agencies who have need of it. Furthermore, the vehicle inspection program may require information gathered by other agencies. The importance of these types of information to the various programs should guide the administrators regarding the methods of transmission to be used. This can best be explained by illustrations: a. Several traffic agencies in a state keep records of people. Most of these expect or require reports of any change of name or address but, in practice, people often forget to make those reports. Any agency receiving information about such a change should at once make it known to all others. This means that if, during a vehicle inspection, it is found that the operator or owner of the vehicle being inspected is no longer living at the address noted on the operator's license or vehicle registration certificate, the appropriate agency should be notified.	

20458

	REFERENCES
(1) Field supervisors should constantly be reminding mechanic-inspectors to check on the correctness of addresses.	
b. In order for a vehicle to be registered it should first have passed an inspection within a specified time. Coordination between vehicle inspection and vehicle registration records should provide the means of enforcing this requirement.	
c. Mechanic-inspectors are usually required to be licensed drivers. If such a person's drivers license is suspended or revoked, he is also disqualified as an inspector. Therefore, it is important that suspension information reach the vehicle inspection agency. To do this effectively the records system should be so designed that appropriate notations are made in an operator's license file when he is certified as a mechanic-inspector.	

	REFERENCES
4. A common experience of management consultants in reviewing communication procedures is the discovery that the majority of forms and reports in use are no longer fulfilling the purpose for which they were intended. In accomplishing what is being suggested in this section, the administrator must be wary of over communicating through forms. The volume of information being processed within and through the vehicle inspection program, a volume of which will most surely increase before it levels off, suggests emphatically the need for electronic data processing. The lack of EDP in the majority of existing vehicle inspection programs has hindered the evaluation of the overall effectiveness of the programs in the past. However, even those states making use of EDP find that it introduces a delay. It is the time required to transcribe data from the data collection forms to punched cards or tapes so that the automatic machinery can digest it. If an agency is now using EDP, or is contemplating its use, the administrators, records analysts, and system programmers should consult on the	Ref. #2 - p. 18

	REFERENCES
information to be recorded so that waste in effort and money will be kept at a minimum. Fewer kinds of forms, forms with data always in the same place, and forms with precoded data all help. In a repetitive type of operation such as noting vehicle defects, input instruments should be considered which can be optical scanned with the data automatically encoded into the system. a. This once again emphasizes the importance of the field supervisors' properly performing their functions of inspecting and training. 5. The next page contains a schematic diagram of processing information connected with the inspection of a vehicle. It should be used by the instructor to solicit suggestions from the class as to the ideal, or the realistic, procedure which should be adopted locally. Similar flow charts should be developed for the processing of information concerned with the certifying of inspection stations and the inspectors.	

From the audit file vehicle ownership can be identified through inspection sticker number. Also, statistical reports as to serial numbered forms may be compiled.

	REFERENCES
6. Exhibits 15 - 35 of this unit are input reports which the Traffic Institute has suggested should be a part of a periodic motor vehicle inspection records system. As with the previously listed output records, these input sheets are designed so that they can be used by the instructor for project assignments or classroom participation. The second section of each sheet has space for the class to note whether or not the agency now is gathering this input information and the estimated number of such inputs each year. There is also space for the evaluation of the existing input data, and if a deficiency is noted, space for suggested requirements for improvement. Codes which could be used for this evaluation are:

	REFERENCES
Requirements A: Form design or form standardization B: Adaptation to new processing method C: Adapt to local or broader use D: Funds, administrative decisions The instructor should consider having the class rate the information listed in the identification and description columns according to its importance to the overall program. Codes which can be used for this are: " This is a must piece of information ' This is a should have piece of information No mark is a nice-to-have piece of information F. Management by Exception 1. Earlier it was said that management by exception is one of the services which a records system can perform. Now that the student has an idea of the amount of	

20464

	REFERENCES
information which will be put into the vehicle inspection record system, it is time to again suggest that supervisors, at all levels of the management heirarchy must know what decisions they are allowed to make and should ask the records system to alert them to situations which require their attention. In practice, management by exception usually means referring minor unusual developments to supervisors and middle management; but if the exceptional situation persists or becomes aggravated, it is referred to the chief administrator or "top management".	
2. The records system, however competent, cannot make plans and set goals; it should not establish standards. These are duties of the people who use reports put out by records systems. But the records system can and should call attention to deviations from norms or averages and sharp or prolonged changes in trends.	
3. Exceptions are usually related to one or more of four bases of comparison. Supervisors should be aware of these so that	

20465

	REFERENCES
they will be able to ask the records personnel to channel meaningful information to their level of operation. a. Plans, goals, time schedules intended or hoped for. The administrator must know if plans are not being carried out, but does not need to be repeatedly told that all operations are according to plan. A goal of vehicle inspection programs is to correct vehicles which are not safe as determined by an inspection. If this control is to be effective there should be some way to know what "failed" vehicles continue to be operated without ever passing an inspection. Likewise, supervisors should know if a station in their area is constantly passing vehicles which had been rejected elsewhere. b. Standards and guides. Standards of motor vehicle safety are established within the inspection program in the belief that adherence to them will be	

	REFERENCES
beneficial. It is important to discover instances in which the standards are not being met, and to take necessary corrective steps. The motor vehicle inspection program should be helpful in determining whether manufacturing standards are being met by alerting the administrator to unusual numbers of defects being noted within one model of vehicles. (1) To do this the administrator would first have to decide when defects become unusual or exceptional and so notify the system. c. Trends. It may not be practical to say that a vehicle inspection program of certain magnitude will definitely reduce traffic accidents by "X" percent a year for the next "X" years, but we can watch the number of accidents occurring and get some idea if vehicle inspection is having any effect on the problem. Trends in work performance and trends in the rate at which a problem is responding to control or	

20467

	REFERENCES
continues to grow are especially important to an administrator; they tell him if he is gaining or losing in his efforts to meet standards. Trends are extremely important as guides when management personnel must intervene and seek to correct lack of satisfactory progress toward meeting standards or achieving goals. In order to make the most efficient use of trends, the user should tell the records system when it is to consider the trend unusual so that the records system may then notify the user that his attention is required.	
d. Deviation from norms. Norms are related to standards; a standard represents a kind of "normal" situation. Then non-conformance is a deviation from this norm. Norms also represent the mean or average of observed experience. The supervisor should be concerned when one of several units performing the same functions under his direction proves to be "different" in some way or another. As an example: it may be that a vehicle	

	REFERENCES
inspection station never shows any repairs required by vehicles which are inspected.	
4. When asking the records system to alert him to an exceptional condition warranting his attention, the supervisor should make sure that he is not getting changes which are due to chance or which have no real statistical significance. An example would be the supervisor who asks to be notified if any station in his area shows a 25% increase or decrease in its monthly reject rate. This supervisor is notified of a 50% change in one of his stations, and on investigation finds that the station, for an isolated reason, inspected and passed one vehicle during the first time period, and during the second time period inspected two vehicles and rejected one of them. If a change such as this is reported it should be clearly marked as not being a significant or reliable change. The same rule applies in reporting before and after accident experience to indicate the effect of vehicle inspection.	

20469

	REFERENCES
5. There are procedures for determining whether or not percent changes are statistically significant. One such procedure is on the next page.	

20470

It is important not to become excited about changes which are probably due to chance. There are statistical tests to evaluate the probability that a change is due to chance. The chart above illustrates such a test. If the percent change related to the number of accidents or other events is below the curve, the probability is greater than 1 in 20 that the change is due to chance. (From Michaels, Richard M., "Two Simple Techniques for Determining the Significance of Accident-reducing Measures" in Traffic Safety Research Review, June 1960)

EXHIBIT XV

DATA FOR RECORDS

(Unit Input)

Title: MV inspection report

Obtained: Periodically (annually) when owner presents vehicle for inspection

Initiated by: Inspector in inspection station

Existing form: Yearly number:

Sufficiency:

Requirements:

Element	Identification	Description
Motor vehicle	Manufacturer, division* Registration number* ID Number	Model year Odometer reading
Inspector	Signature ID Number Station Number	
Approved	Date Place Number of sticker	Yes, No Yes, after repair
If disapproved, why		List of items rejected
Attempts to qualify		Number of previous disapprovals

May be as a list, one line per vehicle, or as individual reports

NHSB MANUAL 1, IV, 9b(2)(b)

20487

EXHIBIT XVI

DATA FOR RECORDS

(Unit Input)

Title: Vehicle mileage

Obtained: When vehicle is inspected

Initiated by: Inspector

Existing form: Yearly number:

Sufficiency:

Requirements:

Element	Identification	Description
Vehicle	Manufacturer, division* Registration number* ID Number	Model year Body style
Mileage		Odometer to nearest 100 miles

NHSB MANUAL 1, IV, 9b(2)(b)8

20488

EXHIBIT XVII

DATA FOR RECORDS

(Unit Input)

Title: Original application for MV inspector

Obtained: When person wants to become MV inspector

Initiated by: Applicant (or station on his behalf)

Existing form: Yearly number:

Sufficiency:

Requirements:

Element	Identification	Description
Application	Date	4-tired vehicle Motorcycle Truck (6 or more tires) Tractor and trailer Bus School bus
Applicant	Full name Residence address DL Number - SS Number Signature	Sex Date of birth
To work in	Name of establishment Address	
Education (highest grade completed)	Name of school City or town Date (year)	Elementary Secondary College Technical Other
Previous application	Date of last Place	How many previous Last approved or disapproved
Previous approval		Revoked Lapsed

The description above of the classes of vehicles applied for is suggestive. Program requirements in any state would dictate the exact classification for which the MV inspector is applying.

20489

EXHIBIT XVIII

DATA FOR RECORDS

(Unit Input)

Title: Approval original application MV inspector

Obtained: When application received

Initiated by: Examiner, inspector, reviewer

Existing form: Yearly number:

Sufficiency:

Requirements:

Element	Identification	Description
Applicant	Name Number	
Examiner	Signature ID Number Department	Title
Basis of judgment		Information from application Supporting documents Tests Recommendations Work record
Approved	Date Place	Yes, No
If disapproved, why		Training, experience Failed tests Personal record*
Examination	Date Place	
Attempts to qualify		Number of previous disapprovals

A list of documents supporting approval or disapproval should appear on the form but are not entered in the working record.

NHSB MANUAL 1, IV, 9b(1)(c)

20499

EXHIBIT XIX

DATA FOR RECORDS

(Unit Input)

Title: Application for scope change MV inspector

Obtained: When additional qualification is desired

Initiated by: MV inspector

Existing form: Yearly number:

Sufficiency:

Requirements:

Elements	Identification	Description
Application	Date	Change desired
Inspector	Name Current address DL Number - SS Number Signature	

This input is unnecessary if every inspector is qualified to inspect all kinds of vehicles, in other words, if there is only one kind of inspector.

EXHIBIT XX

DATA FOR RECORDS

(Unit Input)

Title: Approval of scope change, MV Inspector

Obtained: When application for scope change received or to approval reinstatement after suspension

Initiated by: Examiner, inspector, reviewer

Existing form: Yearly number:

Sufficiency:

Requirements:

Elements	Identification	Description
Inspector	Name DL Number - SS Number	
Examiner	Signature ID Number Department	Title
Approval	Date Place	Yes, No
Basis of judgment		Information from applicant Supporting documents Recommendations Tests Driver record
If disapproved, why		Physical condition Education, experience Personal record Failed tests Driver record
Attempts to qualify		Number of previous disapprovals

A list of documents supporting approval or disapproval should appear on the form but are not entered in the working record. Input not necessary if all inspectors are fully qualified to inspect all vehicles.

EXHIBIT XXI

DATA FOR RECORDS

(Unit Input)

Title: Renewal (updating) MV inspector

Obtained: Periodically before expiration (annually)

Initiated by: Inspector or station on his behalf in response to request from PMVI printout

---

Existing form: Yearly number:

Sufficiency:

Requirements:

Element	Identification	Description
Application	Date of expiration	
Inspector	Name Current address DL Number - SS Number Signature	
To work in	Name of station Address	
Changes from	Former name Former address Former station	
Desire to continue		Yes, No

SAVING A LIFE

BY ARTIFICIAL RESPIRATION

THE AMERICAN NATIONAL RED CROSS

If victim is not breathing, begin some form of artificial respiration at once. Wipe out quickly any foreign matter visible in the mouth, using your fingers or a cloth wrapped around your fingers.

MOUTH-TO-MOUTH (MOUTH-TO-NOSE) METHOD

Tilt victim's head back. (Fig. 1). Pull or push the jaw into a jutting-out position. (Fig. 2).

If victim is a small child, place your mouth tightly over his mouth and nose and blow gently into his lungs about 20 times a minute. If victim is an adult (see Fig. 3), cover the mouth with your mouth, pinch his nostrils shut, and blow vigorously about 12 times a minute.

If unable to get air into lungs of victim, and if head and jaw positions are correct, suspect foreign matter in throat. To remove it, suspend a small child momentarily by the ankles or place child in position shown in Fig. 4, and slap sharply between shoulder blades.

If the victim is adult, place in position shown in Fig. 5, and use same procedure.

SUBJECT: TRAINING - A FUNCTION OF MANAGEMENT

HOURS: 8

OBJECTIVE: To develop the student's understanding of management responsibility to up-grade personnel performance through training; to increase ability to implement training programs; and to acquaint the student with the responsibility of training to provide staff service to management.

METHOD OF INSTRUCTION: This presentation is designed to be given by the lecture method. Students may be divided into groups for the purpose of designing a training program for field supervisors and station supervisors. They should also develop criteria for evaluating such a training program.

INSTRUCTOR'S GUIDE

(TRAINING - A FUNCTION OF MANAGEMENT)

I. INTRODUCTION

A. Training is an essential part of personnel management. "Personnel Management" is an integral part of "administration."* Due to the placement of the function of motor vehicle inspection within the organizational structure of a state government, it is assumed that the processes of training for PMVI will be part of a larger program directed toward training of employees of a number of divisions within the motor vehicle or public safety department of a state. Instruction should emphasize that this in no way reduces the need for training, nor does it affect the management role in training.

*Ref. #1, Sec. 3.5.1 through 3.5.5

20509

	REFERENCES
II. PRESENTATION	
A. What is Training?	
1. Training is a process used to help employees acquire the attitudes, knowledge, skill or experience needed to carry out the specific tasks to which they are or may be assigned. Training is concerned with motivation, morale, cooperation, obedience to procedures, compliance with orders and acceptance of policies and many other facets of operation which cause an organization to carry on its commitments.	
III. ESTABLISHING A CLIMATE FOR TRAINING	
A. The Administrator must Create an Atmosphere for the Acceptance of Training.	
1. Members of his organization must be aware of his support of training and his belief in the value of the process of training.	
a. Training is often thought of as a "stooge" activity for management.	
2. The administrator must be willing and able to convey the same attitude to his superiors for:	
a. Budgetary reasons	

	REFERENCES
b. To justify personnel assignment to training section.	
c. To justify in-service and "up-grading" training.	
B. The Administrator Must Formulate and Publish a General Policy Statement Relating to the Need for Training and the Value of it.	
1. Such a policy gives the training function a recognized "status" structure within the "staff" functions of the organization.	
a. This is extremely important in PMVI programs because a large portion of the budget is personnel. Therefore, an administrator can obtain the greatest return on his money through improvement of human resources. In addition, employees derive necessary job satisfaction by being able to perform well.	
C. The Administrator Must Provide for a Realistic Training Budget. Realistic in Cost, Time, Number of People to be Trained and Re-trained.	
1. The important categories in a training budget are:	
a. Provisions for space, materials, equip-	

	REFERENCES
ment and training personnel.	
b. Who is to be trained and:	
(1) Salary considerations of training staff.	
(2) Salaries of personnel while in training (if Performance Budgeting).	
c. Provisions for guest instructors.	
d. Cost of housing students.	
e. Cost of meals and travel.	
f. Without a program and adequate budget, training becomes a "step-child" of other functions and often is seriously neglected for lack of money and direction.	
D. The Administrator Should Require a Formalized Schedule of Training.	
1. Training formally scheduled permits supervisors to plan their personnel schedules in such a way as to be able to assign personnel to training without having to establish "emergency" measures to cover the tasks to be done while their people are away in training.

	REFERENCES
2. A further purpose is to allow field personnel to advise non-departmental people when training will be scheduled so that they -(the non-personnel) can schedule their appearance in training sessions. (In PMVI the agency may conduct mechanic-inspector training for new licensees or refresher training for mechanic-inspectors who are licensed.)	
3. A training schedule may be made up as little as three months in advance or for as long as the budget period, which may be two years.	
E. Training, as a Staff Function, Should be so Structured in the Department that there is Adequate Means for Coordination and Communications with those Division within the Agency that use the Training Services. This Positioning of the Training Function is an Administrator's Responsibility.	
1. The Periodic Motor Vehicle Inspection function is normally a section or function of a larger agency, and training of PMVI personnel may require special emphasis in coordination.	

	REFERENCES
F. The Organization of the Training Section is a Matter of Concern for the Administrator. 1. Must be so organized that all elements using the service have emphasis placed on their training needs in proper proportion to their needs. A training section that is staffed with specialists from the driver license field or state police might well display less zeal for PMVI than for their own speciality. This will result in a down-grading of the PMVI function.	
G. A Training Advisory Committee can be Particularly Helpful to the Administrator. 1. An advisory committee composed of persons responsible for and interested in the inspection program can assist in identifying and evaluating training. 2. Because of the nature of most inspection programs the committee should consist of representatives from within the organization such as a field supervisor and a station supervisor. In addition, an owner or manager of an authorized inspection station and an inspector-mechanic should be on the committee.	

	REFERENCES
a. Each of these people have a personal stake in the success of the inspection program.	
IV. THE PMVI ADMINISTRATOR'S RESPONSIBILITIES FOR TRAINING	
A. Administering the Training Program.	
1. Planning	
a. Develop policies for training.	
b. Draw up rules and regulations relating to training.	
c. Set objectives and broad programs for training.	
d. Determine personnel needs.	
e. Determine facility needs.	
2. Organizing	
a. Assigning personnel and facilities.	
b. Allocating functions to personnel.	
c. Establishing the training function in the departmental organization. (In determining the position of training within the organization the size of the PMVI section, its positioning	

20515

	REFERENCES
within a larger parent organization and the role that the parent organization plays in providing training for all branches of the parent organization are factors for consideration.)	
3. Staffing	
a. Selection and assignment of instructors.	
b. Improving instructors through consultation, indicating problem areas and training needs.	
c. Improve instructors through recommending courses of action and by providing supervision.	
4. Directing	
a. Directing the activities of subordinates, non-technical staff, in-house instructors, counselling "outside" instructors.	
b. Directing the student body. (Often aided by written rules, particularly on short-term training sessions.)	
5. Coordinating	
a. Assigning personnel and facilities for most effective use.	

20516

	REFERENCES
b. Training activities with staff and command activities. (The implication here is that there must be a willingness of organizational staff to keep training informed of needs and programs which may create scheduling problems; of departmental programs which will have a direct bearing on the training function. (1) A method for keeping training informed of needs occurs in the control processes of the organization; staff conferences, inspection processes and other techniques used in Control, point up training needs. The problem of program operations which may interfere with training schedules can be resolved in proper staff functioning. As programs are scheduled concurrence from interested divisions can be obtained on the basis of manpower available and time scheduling.	

20517

	REFERENCES
c. Coordinating departmental employee training schedules with training department has scheduled for others. It is not unusual in PMVI for the station supervisor to have established a program of retraining for inspection mechanics. It would be possible for that station supervisor to be scheduled for departmental "in-service" training during the same period unless coordination existed.	
6. Reporting - without an adequate system for reporting the organization loses much in the needed exchange of information.	
a. The administrator must seek ways to be sure the information concerning operations is reaching him. This reporting to the administrator is accomplished through a number of management techniques; some of these are: inspection, statistical reporting, summaries of activities, staff conferences, staff visits, and control techniques.	
At the same time the administrator is seeking ways to be informed of operations,	

	REFERENCES
the organization's operations are being "explained in the field." In large organizations such a flow of information may be in the form of bulletins, training flyers, or other brief news releases. The general staff conference also provides the opportunity for exchange of information but often the press of the total business causes omissions and lack of complete communications.	
7. Budgeting for training. a. The administrator interprets training costs and justifies them. b. He attempts to assure the best use of funds. c. He works toward assuring adequate training materials and facilities. (It is often said that when competition for the budget dollar gets keen, training and training facilities get short shrift.)	

20519

	REFERENCES
B. The Administrator Should Designate one Person as being Responsible for Development of Courses and Curriculum...Hereafter Designated as Training Director. (The Training Function Does not Necessarily have to be a Separate Unit or Division.) 1. Identifying training needs. (This requires a constant communication with other staff, a review of operations, a study of departmental evaluation and inspection reports.) 2. Establishing attainable objectives. (In PMVI as in any other governmental organization budget, time and manpower limitations will be a factor in determining to what degree training will be carried on.) 3. Selecting and organizing course content that can be used to attain objectives. 4. Developing student activities that will assist in attaining objectives. 5. Creating the evaluation device that will aid in determining how nearly training objectives have been attained. (The examination, the demonstration, an analysis of field performance, etc.)	

	REFERENCES
C. The Training Director Provides Course Direction	
1. Schedules course operational details, types of programs, hours, subjects, objectives, etc.	
2. Assures availability of facilities, equipment, etc.	
3. Selects instructors, explains objectives, plans for alternates in case of emergency.	
4. Arranges for preparation of student and instructor reference material.	
5. Establishes rules for course operation and conduct of students.	
6. Keeps program on schedule, introduces instructors, monitors their work.	
7. Keeps superiors informed on progress.	
8. Records deficiencies in operations in order to correct for "next time around."	
D. The Training Director Evaluates Results of Instruction.	
1. Determines extent of learning by students.	
a. As course progresses.	
b. At conclusion of the course.	20521

	REFERENCES
2. Follows up training (job performance). If training is directly related to job performance. a. Establishes S.O.P.'s for reports from the field. b. May make an on-the-job review. c. Review findings as reported by supervisors, inspection officers and management.	
E. Administrator sees that there is a System for Reporting and Recording Training Information. 1. Abilities of personnel, developed through training and subsequently reported, need to be at management's fingertips. A good technique is for the training division to submit a written report to the administrator on each student in training, outlining his performance, his abilities and limitations, and itemizing any special talents or traits that management may need to know. It is well for management to know who can perform and who cannot. The larger the organization the less top management is likely to know about individual abilities in lower echelons.

	REFERENCES
2. Comparison of performance with training is essential to successful personnel management. a. This comparison can be made through supervisory techniques. Example: Study of activity reported, evaluation of reports submitted, analysis of employee evaluation forms, review of letters of condemnation and commendation, etc. 3. Supervision of personnel can be aided by information reported by the training division. a. Supervisor's review of training's evaluation of a student can provide clues as to the special areas where special attention may need to be directed. An example of this technique: "The Training Division reports that the new employee has shown some ineptitude in report writing. The suggestion is that special attention needs to be directed to this phase of the employees work. Similarily, training may note that an employee should be good in public speaking. In either case the employee's supervisor, then, has a better understanding of his subordinate's abilities.	

	REFERENCES
4. Without adequate "feed-back" from the field, errors can be perpetuated. a. The failure on the part of supervision to report inadequacy of performance on the part of employees, as it is related to his training, leaves training with no idea that certain concepts they are teaching are either not practical, or are in error.	
5. Records provide useful information for future use in: a. Reporting what was done this time. b. Appraisal for consideration in next presentation. c. Shortening preparation time. d. Guide future planning. e. To preserve data on personnel, individual achievement, etc.	
V. TRAINING AND SELECTION A. Training Complements the Selection of, and the Evaluation of Employees. 1. The selection process determines who is to be trained. At the same time it defines the	

	REFERENCES
basic qualities needed. Training, then, has the obligation to refine these basic qualities so that the beginner can function at his best.	
2. The desirable traits, skills and abilities needed are first defined through a job description process. a. By establishing job descriptions, training has a better guide for determining what the individual must do and what he must know in order to do it.	Ref. #3, pp. 21-58
3. Administrator - management has obligation to provide job description.	Ref. #1, Sec. 3.6.1 pp. 1-32
4. Training provides management with added refinement in determining candidate qualification. It can: a. Reveal employee's special abilities or lack of same. (1) Memory (2) Initiative (3) Enthusiasm for job (4) Ability to get along with others.	

	REFERENCES
b. Close observation by training staff allows for screening out those who are obviously not suited. In the training sessions the instructors can often detect a lack of initiative, an inability to work with others, over-aggressiveness, poor grammar, diction, and ability to express ideas. (Instructor: question class about employment procedures and what qualities the usual detection process can reveal.) (1) Employment procedures in many instances are not designed to disclose candidate abilities. (2) Stress situations will often bring out the true measure of the employee (some training directors plan stress situations in order to observe student reaction). The instructors may do this by inserting obviously difficult questions into the class or by playing the role of the "devil's advocate" to determine how the student reacts.	

	REFERENCES
(a) Role playing within the class can also aid in measuring the student's abilities. A classic example of this in PMVI is the situation with which the station supervisor is often confronted. The citizen who complains about the inspection process in general, then about a particular inspecting station, a specific inspector-mechanic, and finally about an inspection item within the inspection standards.	
(3) Traits which can be detected by training personnel must be carefully considered before final judgment is rendered. Examples:	
(a) Laziness may be due to temporary illness.	
(b) An apparently sharp individual may be, for the moment, in a field where he has had ample opportunity for experience and learning.	

20527

	REFERENCES
(c) The caution here is for training personnel to compare notes, make sound evaluations.	
5. Training provides orientation for the employees.	
a. The employee performs better when he understands his organization; the objectives; its regulations; what is expected of him; what he can expect from others; etc.	
b. The employee develops confidence in his ability to do the job -- to perform.	
6. Training can provide clues for identifying employees who may display qualities desirable in higher positions, or in other positions within the organization.	
a. The Director of Training, and other training personnel, are constantly on the alert for outstanding students.	
7. Training can provide service to employee who is changing to a different job.	
a. In motor vehicle inspection many of the new station supervisors may be men whose work experience was not in the inspection field.	

	REFERENCES
b. Obviously these new supervisors must be "brought up" to an acceptable level of understanding of their jobs and all facets of same.	
8. Training plays an important role in providing education for men who are "moving up" within the organization.	
a. Supervisory and management training.	
b. Involves not only the technical aspects of the job but attitude changes.	
c. Recognition of added responsibilities and added authority.	
9. An analysis of merit ratings can identify areas in which personnel need improvement. Training may be able to meet this need.	
10. Training provides a principal source of "upgrading" of personnel in order that the individual's rating may be better.	
a. If an individual improves as a result of training - education, it strengthens his belief in the system.	
b. His job is better understood, easier to perform and more satisfying.	

20529

	REFERENCES
11. Training serves as an example of personnel management policies of the department in operation.	
a. Well operated school involves good management; indicates management's interest in employee welfare.	
VI. TYPES OF TRAINING (To Provide Training for PMVI)	
A. Basic Training Considerations	Ref. #2, pp. 16-33
1. In most situations the motor vehicle inspection program would not be of sufficient size to justify a basic training school of its own.	
2. The training that is needed by station supervisors is very similar in many respects to that needed by law enforcement officers. This is especially true of such areas as report writing, case preparation, rules of evidence, investigative techniques, etc. Therefore, the administrator should take advantage of the training program of the state police or highway patrol.	
a. However, the administrator should not consider this training sufficient. He must include additional in-depth instruction on the inspection rules, procedures,	

	REFERENCES
testing of equipment, etc.	
3. The availability of training elsewhere:	
a. American Association of Motor Vehicle Administrators training.	
b. Regional training seminars.	
c. Training conducted by the parent organization. Examples: the Department of Transportation, a Department of Public Safety; - have an academy and all training is conducted there.	
d. In PMVI the manufacturers of testing equipment can provide training.	
e. The automobile manufacturers should not be overlooked as a source of specialized training on functions of component parts.	
4. Course content is an obvious management consideration. Management must consider what is essential; what would be needed for improvement beyond basic needs; and what is needed for the future.	
5. The time available to be allocated to PMVI, if in a course being conducted for personnel	

	REFERENCES
whose first assignment may not be in PMVI, as an example:in state police academies the PMVI function is a part of the total job responsibilities, and limited time on teaching this subject may be assigned. If the new employee is to go directly into PMVI, then greater time should be allocated to his training.	
6. Staff and assistance available are important in establishing recruit training programs.	
7. Budget money and facilities are essentially a management consideration in establishing any type training.	
8. Delegating responsibility for the training is a consideration. Must be done before almost any other consideration, in order that coordination and planning can proceed in an orderly fashion.	
9. Selection of program type is a consideration. a. Number of hours and days in classroom. b. Classroom vs field time vs combination of same in order to best prepare the student.	

Case of the Cluttered Corner. 10 min., 16 mm., sd., b & w, 1958. Associated Films, Inc., 347 Madison Avenue, New York 10017.
Summary: Broken leg leads to finding out how and why the corner got cluttered.

Cause and Effect. 15 min., 35 mm., film strip, sd., b & w, 1957. Zurich Insurance Company, 111 West Jackson Blvd., Chicago 60604.
Summary: Typical occupational accident prevention.

Close Shaves. 15 min., 35 mm., film strip, sd., b & w, Zurich Insurance Co., 111 West Jackson Blvd., Chicago 60604.
Summary: Near accidents are warnings of danger.

Communication for Safety Series. (4 films). National Safety Council, 425 North Michigan Avenue, Chicago, 60611.
No. 1. *Let's Talk About Safety.* 10 min., 16 mm., sd., b & w, 1959.
Summary: Talking about safety can be a helpful habit.
No. 2. *Take a Talkie–Brief.* 10 min., 16 mm., sd., b & w, 1959.
Summary: Ten minutes a day devoted to safety talks.
No. 3. *Setting 'Em Straight.* 10 min., 16 mm., sd., b & w, 1959.
Summary: How to correct worker's unsafe habits without causing hurt feelings.
No. 4. *Let Everybody Help.* 10 min., 16 mm., sd., b & w, 1959.
Summary: Cooperation comes when workers know their ideas are wanted.

Current Facts. 22 min., 35 mm., film strip, sd., 1961. Liberty Mutual Insurance Co., 175 Berkeley Street, Boston, Mass. 02117.
Summary: Causes of electric shock accidents from cords, appartus, and portable devices.

Don't Take Chances. 13½ min., 16 mm., sd., color, 1963. International Film Bureau, Inc., 332 South Michigan Avenue, Chicago 60604.
Summary: Dramatization of the fatal result of chance taking.

Easy Does It. 15 min., 35 mm., film strip, sd., b & w, 1951. Zurich Insurance Company, 111 West Jackson Blvd., Chicago 60604.
Summary: Handling materials–includes a photo quiz.

Electricity–Principles of Safety. 11 min., 16 mm., sd., color, 1960. Coronet Instructional Films, 65 East South Water Street, Chicago 60601.
Summary: Points out common hazards of electricity and their causes.

Everybody's Job. 15 min., 35 mm., film strip, sd., b & w, 1953. Zurich Insurance Co., 111 West Jackson Blvd., Chicago 60604.
Summary: How a safety committee works.

Falls. 5 min., 16 mm., sd., b & w, Contemporary Films, Inc., 267 West 25th Street, New York 10001.
Summary: Spotlights most common cause of industrial falls.

2028

	REFERENCES
c. In the recruit or beginner class the degree of training, the number of hours, the practical training versus classroom training will be based on the exact position the new employee will fill. It is generally assumed that the beginner will have to understand how to use inspection equipment, what it can do, and cannot do; the reasons for inspecting the component parts; the use and functions of calibrating equipment. He should be given practical field experience in: (1) Inspecting vehicles. (2) Inspecting the work of inspector-mechanics and inspection station operations. (3) In general those things departmental experience indicated are essential for an employee who is just entering the department's service. Future training can be handled at the in-service level.	

20533

	REFERENCES
10. Is basic training to be followed by probationary period? The degree to which you go to determine qualities of beginner will be affected by whether or not you can eliminate him if he proved unworthy during the earliest period of his employment. a. In those departments that operate under a system which allows the administrator to place a man on probation for a specified period of time after his initial employment, the administrator has an opportunity to review the man's abilities, and if he doesn't measure up, he can be eliminated. b. In those agencies where the employee enters the department with tenure immediately after the completion of the recruit school, the administrator must ascertain as best he can whether the new employee is going to be satisfactory. Therefore, the training must provide a deeper insight into the man's abilities and future potential.	

	REFERENCES
B. Regularly Scheduled Refresher Courses: 1. Refresher courses scheduled well in advance to provide management with an opportunity to communicate ideas, new programs, changing objectives, etc. a. Especially important in PMVI because of changing legislation, revision of rules, court opinions, etc. b. Supervisors must be equipped with the latest information and understand the reasons for any changes in rules. 2. Should provide increased uniformity of operation. 3. Provides for upgrading in areas of deficiency. 4. Identifies new policies, procedures and techniques. 5. Problems of conducting annual refresher courses are: a. Decentralization of PMVI personnel creates expense in assembling students. b. Continuity of instruction and instructors may be difficult if a number of sessions are planned.	

20535

	REFERENCES
c. If sessions are planned in which all personnel attend at one time, then station supervision and field operations come to a halt.	
d. Payment for time spent in training, if student attends night sessions, etc. If overtime must be paid for special sessions, then budgetary considerations arise.	
e. Keeping all levels of management informed on exactly what is covered and how covered in the in-service school. (1) Often after an in-service school, line management finds that changes in procedures have been made without their superior's being informed.	
f. Preparing meaningful agendas for discussion.	
g. Nothing kills the quality of in-service training quicker than the presentation of material over and over again. The material must be of sufficient importance to warrant in-service training or none should be held.	

20536

	REFERENCES
C. Continuous In-service Training: 1. Is not practical for decentralized operations such as occurs in PMVI. 2. Would have merit if personnel were within easy commuting distance of training source.	
D. Continuous Training via Training Bulletins: 1. Training bulletins are particularly well suited for inspection training. Employees are decentralized and hard to reach for brief periods of instruction. The bulletin can also serve the dual purpose of an in-house training device and at the same time provide information to inspection stations and mechanics. a. The preparation and publication of meaningful training bulletins requires considerable effort. The material must be meaningful and deal with operations where added information is needed. This added information need is determined by the departmental "feed-back" system, i.e., inspection, activity reports, staff discussions, supervisory reporting, analysis of performance through direct supervision and through study of trends, etc. The	20537

	REFERENCES
reader of such bulletins will ignore the material if it constantly deals in trite subjects for which there is little need for clarification.	
b. They are a good tool when standard format is used in presenting information. Often bulletins are, or become, policy (rules and/or regulations). A bulletin, per se, should never become a policy, or a rule, unless it is so identified and then it should be taken out of the classification of a bulletin and written in the format the department uses for whatever it is to be, i.e., policy, rule or procedure.	
c. The principal purpose is to inform, but when the information is no longer valid then procedures are necessary to see that changes or cancellations occur. (An example of a good training bulletin, prepared by the state of Oklahoma, is attached).	
d. Generally such bulletins are considered to be "how-to-do" information, but can well be used to keep employees informed.	

	REFERENCES
E. Coach-pupil Method of Training: 1. Because of the relatively small number of new station supervisors entering the program at any one time, an effective training technique is to assign a new station supervisor with a field supervisor. a. Provides supplement to formal training. b. Gives student immediate re-enforcement of learning process by reason of coach's guidance. 2. The selection of personnel to act as coach often has a salutary effect on the man selected, (the field supervisor). He will often improve his own performance in order to coach his new pupil. He may thrive on recognition. He teaches, observes, discusses and counsels. On the opposite side of the coin a man selected as a coach who is disgruntled, or not motivated to improve his pupil will do little to improve the pupil. There is need, therefore, for close supervision of the coach-pupil process to determine whether or not the coach is, in fact, doing what he is assigned to do.	

20539

	REFERENCES
3. Coach evaluates and reports on his pupil. Provides good "feed-back" on other training and allows management to decide whether to retain pupil in the job for which he has been selected. The coach should be reporting the student's ability to do the job.	
4. The time element for the coach-pupil status will be related to the amount of previous training and experience the pupil has. Too often the time element is only related to how badly the organization needs a "warm body" in a job.	
a. A rejection of a pupil after two months training can leave a position open until another man is trained and ready to go. If the need is critical the pupil may be approved, although not qualified.	
F. The Training Conference as a Training Technique.	
1. This technique has particular application to the training of inspector-mechanics by the station supervisor. In cases where this technique is used the administrator should provide the station supervisor with written	

	REFERENCES
guidelines on how the training should be conducted. (Sample from Louisiana attached.) This will greatly aid the station supervisor and help to insure uniformity of instruction throughout the state.	
2. The training conference also can work well as a supervisory personnel training technique.	
a. Allows for exchange of views.	
b. Analysis of procedures and concepts.	
c. Stimulates thinking.	
d. Creates awareness of similarities and/or differences in problems, etc.	
e. Instills sense of participation for source of new information and experience.	
3. Group size should be limited to a maximum of 25 men.	
4. Requires skill in discussion leading.	
5. Objectives of the training conference:	
a. Provide inspiration; to engender enthusiasm.	

	REFERENCES
b. To exchange experiences and thusly add new information for participants.	
c. To conduct problem solving sessions; adds expertise to the staff; provides management with insight into problem areas that they may have missed.	
G. Other types of training:	
1. Pre-promotional	
a. Preparatory training for men eligible for promotion.	
b. May include men from a civil service eligibility list; men who have the necessary senority; proven ability, etc.	
c. The question of who attends and who is not permitted to attend can be a morale factor in a department. The personnel of the department should have a clear understanding of the eligibility for pre-promotional training, i.e., in the cases of civil service list there may be an inclusion of the top men on the list and exclusion of others lower on the list.	

Falls Are No Fun. 10 min., 16 mm., sd., b & w, 1957. Associated Films, Inc., 347 Madison Avenue, New York, 10017.
Summary: Cartoon treatment of situations resulting in falls.

First Aid. 29 min., 16 mm., sd., b & w, American Red Cross, 615 North Asaph Street, Alexandra, Va., 22314 or inquire of local chapter.
Summary: Basic life-saving and related skills taught in revised standard first aid course of American Red Cross.

The Guy Behind Your Back. 20 min., 35 mm. filmstrip., sd., b & w, 1953. Air Reduction Sales Co., 60 East 42nd Street, New York 10017.
Summary: The fundamental approach to safety for operators of oxyacetylene welding and cutting equipment. Cartoon style.

Heads You Win. 15 min., 35 mm. filmstrip, sd., b & w, 1954. Zurich Insurance Company, 111 West Jackson Blvd., Chicago 60604.
Summary: Safety in the small shop.

Here's How. 15 min., 35 mm. film strip, sd., b & w, 1950. Zurich Insurance Company, 111 West Jackson Blvd., Chicago 60604.
Summary: Shows how to do various industrial jobs safely and efficiently.

How to Avoid Muscle Strains. 15 min., 16 mm., sd., b & w, Bray Studies, Inc., 729 Seventh Avenue, New York 10019.
Summary: For industrial, school and general public. Basics of lifting and handling for prevention of back and muscular injury.

How to Have an Accident at Work. 8 min., 16 mm., sd., color, 1960. Walt Disney Productions, 16 mm Film Division, 350 S. Buena Vista, Burbank, Calif. or 545 Cedar Lane, Teaneck, N.J.
Summary: Donald Duck disregards all rules on the job and blames fate for his troubles.

Human Factors in Safety. (series of 4). 10 min. each, 16 mm., sd., color, and b & w. National Safety Council, 425 North Michigan Avenue, Chicago, 60611, 1965.
Summary: Teaches fundamental concepts of human behavior as related to accidents.

The Key Man Series. (4 films) Associated Films, Inc., 347 Madison Avenue, New York 10017.
No. 1. *Point of No Return.* 10 min., 16 mm., sd., b & w, 1961.
Summary: Study of consequences of an accident.
No. 2. *You're the Key Man.* 10 min., 16 mm., sd., b & w, 1961.
Summary: Decisions and attitudes of foreman can result in greater safety consciousness in workers.
No. 3. *It's the Little Things that Count.* 10 min., 16 mm., sd., b & w, 1961.
Summary: Editor of plant magazine finds out who was most responsible for the winning of top safety award.
No. 4. *People are the Puzzle.* 10 min., 16 mm., sd., b & w, 1961.
Summary: Knowing your people is the key to accident prevention.

	REFERENCES
(1) If civil service lists are not a factor in the selection/exclusion process, it may be based on an employee evaluation system or "senority" although senority, per se, is not a valid reason for promotion.	
(2) If the number of men for pre-promotional training is small it might be wise (morale-wise) to include all men in the training who are eligible for promotion.	
d. Pre-promotional training giv es management a final opportunity for evaluating eligible personnel before promotion, for in this training situation management can again evaluate the individual.	
2. Post-promotional training	
a. Management's opportunity to see that new station supervisors, field supervisors, or staff personnel are adequately trained to meet the demands of their new position.	
b. Course content can, in part, be determined by an analysis of past performances	

20543

	REFERENCES
of new supervisors. In PMVI, with a wide decentralization of personnel, personal responsibility must be stressed.	
3. Supervisory training - training for men in the supervisory capacity, but who are not necessarily newly promoted supervisors.	
a. Periodic retraining tends to keep the supervisor alert to his job responsibilities and should improve his operations.	
b. The supervisor is the link between operations and management. The time and effort expended in improving supervision will "pay off" in improved operations at the operational level and a smoothing out of management problems as the supervisor gets management's desires implemented at the operational level.	
4. Command training - headquarters staff level training.	
5. Management level training	
a. For personnel who have potential for upward movement into managerial positions.	

	REFERENCES
6. Technical training, both within and outside the department. a. In PMVI, automotive mechanics would be an example. b. Functions of inspection equipment. c. Complete understanding of motor vehicle standards.

SUBJECT: PLANNING - A FUNCTION OF MANAGEMENT

HOURS: 12

OBJECTIVES: To develop a student's understanding of the need for planning; of levels and types of plans; of steps in the planning process. To identify factors which influence the reliability of planning.

METHODS OF INSTRUCTION: Recommended instructional procedure includes project work in developing a plan. Principal instructional method is lecture presentation.

In this presentation special emphasis needs to be placed on the project work in order to get the student involved in the actual processes of planning. Classroom projects or assignments outside the classroom should provide the student with the dual opportunity of preparing plans as well as developing work that has value in broadening his ability to administer or supervise periodic motor vehicle inspection.

Suggested areas of assignment of project work may include planning for:

1. Changing from once a year inspection program to a six months program.

2. The addition of added inspection requirements, i.e., component parts to be inspected.

3. Presentation of a program to the legislature for the purpose of restoring certain elements of the program which have been lost.

4. Future needs of the inspection program based on anticipated growth and/or legislative or administrative action.

20548

INSTRUCTOR'S GUIDE

(PLANNING - A FUNCTION OF MANAGEMENT)

I. INTRODUCTION

A. Purpose of this session

1. Planning is an essential element of all phases of administration and at all levels of operation within an organization. The primary differences in planning that exist from one level of management to another are those of scope and time.

2. The student should develop an understanding of the necessities of planning and how the successful accomplishment of an organization's objectives are inter-related to that organization's ability to plan for contingencies, both short-term and long-range in scope.

3. Planning occurs at all levels in an organization. These levels may be defined as administrative, supervisory and operational.

20549

	REFERENCES
II. PRESENTATION (Planning position in management)	
A. Definition of planning	Ref. #5, pp. 15-81
1. Planning is basically deciding in advance what is to be done and how it is to be done. A plan is a projected course of action.	
2. Planning involves ends and means -- ends inevitably involve values (results).	
a. Means involve resources and availability of personnel.	
3. Normally involves at least these considerations:	
a. Awareness of an action needed.	
b. Investigation of those factors which have or will create the need and an analysis of action and alternatives to meet the needs.	
c. A proposal for action.	
d. A final decision.	
B. Relationship of plans to other activities of management.	Ref. #5, pp. 15-17
1. Plans and planning are an integral part of all activities of management.	

	REFERENCES
a. The separation of the planning function into a separate unit still does not eliminate the necessity of all units of the operation from participation. (Charts or slides showing organizational structure where (1) planning section is a separate unit, and (2) where it is a part of each operation.)	
b. Staff personnel must provide statistics, information, judgments. (Consulting service to the planning section.)	
c. Suggest techniques.	
2. In a successful operation, planning must be a continuing activity.	
a. Operational overview is a responsibility of planning. Once a plan is implemented and a program on-going, future needs then need reviewing.	
(1) In PMVI it can be expected that vehicle design change will create need for constant re-evaluation of inspection procedures and/or addition or deletion of component parts inspection. (Example: change in front	

	REFERENCES
end suspension could require major change in techniques; elimination of internal combustion engine to affect exhaust emission control, etc.)	
C. Kinds of plans needed	
1. The plans designed to accomplish major goals and/or objectives of the PMVI program. (The implementation of policy.)	
a. Examples: Safe motor vehicle equipment on the highways as an objective.	
b. Efficient, effective operation of the PMVI program as a whole.	
c. The implementation of a major change in inspecting techniques.	
2. Single use plans (non-repetitive type function).	
a. May be used to accomplish major goals; often are more clearly related to the accomplishment of a single facet of operation. Examples:	
(1) A plan for adopting a new technique.	
(2) A change in or adoption of new equipment.	

Lucky. 18½ min., 16 mm., sd., color, 1959. Union Carbide Nuclear Co., P.O. Box 1410, Paducah, Ky. 42202.
Summary: Shows how attitudes can affect worker and his job.

Matter of Degree. 13 min., 35 mm. film strip, sd., color, 1957. Crown Zellerbach Corporation, One Bush Street, San Francisco 94119.
Summary: Outlines program for prevention of employer accidents.

Mind Your Back. 13¼ min., 16 mm., sd., color, 1965. Australian News and Information Bureau, 636 Fifth Avenue, New York 10020.
Summary: Demonstrates right and wrong methods of lifting/handling objects.

Painting Safely. 22 min., 35 mm. film strip, sd., color, 1958. California State Compensation Insurance Fund, 525 Golden Gate Avenue, San Francisco 94101.
Summary: Teaches safe practices in the painting trade.

Safety for Sure. 11 min., 16 mm., sd., b & w, U.S. Department of Agriculture, Motion Picture Service, Washington, D.C. 20250 or loan from nearest U.S. Forest Service Office.
Summary: Presents four key points to be taught on any job.

Safety in the Shop. 10 min., 16 mm., sd., b & w, Mogul's, 112 West 48th Street, New York 10019.
Summary: Emphasizes the supervisor's responsibility in teaching and maintaining safe practices.

Safety Management Films Series. (8 films) each: 10 min., 16 mm., sd., b & w, 1963. National Safety Council, 425 North Michigan Avenue, Chicago 60611.
Summary: Series deals with several elements of safety management for supervisors and foremen.

No. 1. *Run the Team*
No. 2. *Plan for Prevention*
No. 3. *Let Them Know*
No. 4. *Mind over Matter*
No. 5. *Safety is in Order*
No. 6. *Bare Minimum*
No. 7. *Guard Duty*
No. 8. *Sell Safety*

School Shop Safety. 14¾ min., 16 mm., sd., color, 1968. Film Associates, 11559 Santa Monica Blvd., Los Angeles 90025.
Summary: Covers the problem of developing safety consciousness in the industrial arts shop.

Shadow of Doubt. 5 min., 16 mm., sd., color, 1965. Pacific Telephone, Room 507, 620 C Street, San Diego, Calif.
Summary: Covers supervisors role in preventing accidents.

So You're New Around Here. 10 min., 16 mm., sd., b & w, 1955. Associated Films, Inc., 347 Madison Avenue, New York 10017.
Summary: Indoctrination of new employees in safe shop.

Stop, Look and Beware. 15 min., 35 mm. film strip, sd., b & w, 1951. Zurich Insurance Co., 111 West Jackson Blvd., Chicago 60604.
Summary: The importance of observing warning signs.

2031 2030

	REFERENCES
3. Plans for routine activities (repetitive operations).	
a. Plans of this type should end up in a procedural type manual or file, in order that there is an understanding of action intended, how to implement it and carry it through.	
b. By placing routine operations in a procedural manual, an organized body of information about PMVI, or any operation, is collected and published so it is at the fingertips of any person within the organization needing it.	
D. Executive must decide: (involves)	
1. What type of plan to be used, to be most useful. (How he will plan.)	Ref. #4, Sec. 6
2. How far will it pay to go in preparing plan. (Cost of planning as benefit to be accrued).	Ref. #4, Sec. 6.21
3. Procedures to be followed in making decisions.	
a. Staff conferences. (Considerations: manpower available; budget considerations.)	
b. Individual staff review of plan. (Importance of objective of plan to	

20553

	REFERENCES
overall objective of the PMVI program.)	
c. Operational level - field supervision concurrence and inputs.	
d. Means available to determine accomplishment of plan objectives.	
III. PLANNING FOR GOALS OR OBJECTIVES (First type of plan).	
A. Levels of planning	
1. In state PMVI operations there are at least three levels at which planning takes place. They are:	
a. The administrative level - at this level major programs are planned; plans which normally are concerned with the overall operations of the department.	
b. The supervisory level - plans at this level generally involve the implementation of procedures that are handed down from the administrator of PMVI. At this level planning may involve such things as improving existing operations; getting better performance through more efficient use of manpower and equipment.	

	REFERENCES
c. The operational level - in PMVI the operational level planning involves the day-to-day performance of the inspection task. Scheduling of manpower, preventitive maintenance of equipment, distribution of reporting falls, etc., fall within this classification.	
B. Necessity for setting up objectives.	
1. Planning must be directed toward stated and understood goals.	
a. In PMVI major goal is reduction of accidents through improvement in condition of vehicles.	Ref. #4, Sec. 1.2.1
b. Must decide what the end product will be.	Ref. #2 - All
2. In planning, the goals will vary with level for which plans are being developed.	
a. Overall objectives of organization is major goal.	
b. The improvement of a record system within PMVI in order to simplify and make the system more efficient is an important goal, but not at the same level as the overall objective.	

20555

	REFERENCES
c. Goals may be simple or complex, generally, depending on the level at which the plans are being developed and the complexities of the program or function being planned.	
C. Factors requiring consideration in setting up goals or objectives.	
1. Budget requirements and/or budget limitations.	
a. A major factor - administrator must consider sources of revenue and logical placement of expenditures to keep a balanced program.	
2. Time deadlines (time requirements to do each part. Critical path method).	
a. Critical path method will set up time estimates for completion of steps in the overall operational scheme of accomplishing the objectives of the plan. The critical path method, when used, then allows the administrator to know from day-to-day where his organization stands in completing the objective. (Ways of setting up critical path method charts differ, but the format is not as important as scheduling operations and	Ref. #1, pp. 21-22

	REFERENCES
then checking on progress through visually related references.)	
b. Generally there are time deadlines for each part.	Ref. #3 - All
(1) Often in PMVI major objectives are identified by legislation or by administrative procedures which identify what should be done by a specific time.	
(2) An example: The legislature passes a statute requiring that all vehicles be equipped with exhaust emission control devices one year after the passing of the legislation. This time designation then sets the limit for completion of development, testing, securing and installing proper testing equipment. To accomplish these objectives there must be established specific time deadlines for each phase, in order that the final time deadline is met. The use of a PERT or other charting method is recommended. With such	

	REFERENCES
a system the administrator can depict where a program stands and more readily determine the reasons for delay, if a delay occurs. c. The various function plans must be coordinated. Examples: (1) Record systems must be ready when inspection procedures start. (2) Equipment must be ready to meet deadline, and training in its use complete. (3) Procedures for inspection routine written and understood before inspection starts. d. Plans and time must allow for station supervisor, field supervisor and operational level personnel to "tool up" for the objective of the plan. 3. In planning objectives there must be recognition of reasonable delays. a. Coordination with other agencies within state government takes time, i.e., a plan and operation that requires that	

	REFERENCES
a vehicle be inspected prior to registration which is being newly implemented would require adequate time for detailed planning on records, forms to be used, training of vehicle inspection personnel and, possibly, tax personnel, etc. (A plan which requires hasty implementation will often disclose glaring difficulties because of lack of coordination.)	
b. Some planning cannot be completed until certain milestones are passed. Examples:	
(1) Legislature decrees that there will be PMVI. Later budget appropriations are made, administrator may find limitations will preclude performing some action he had anticipated.	
(2) Decision to start state-owned inspection operations. Administrator cannot plan buildings, personnel and total budget needs until he determines equipment needs, cost and space requirements, etc.	

	REFERENCES
4. In setting objectives there must be consideration of performance levels or standards to be expected. What can you reasonably expect to do? Other commitments must also be considered. a. Availability of resources and potential resources important. (Manpower, money). b. Reasonable (attainment) goals essential. c. Priorities for performance. (In what order and how do all factors affect this?) d. There will be an adverse effect on quality and possibly quantity if these limitations are not considered. e. Public acceptance can force a major revision in some operations. (1) Example to illustrate this point can be found in a number of states where the administration developed well designed PMVI programs and had to "back off" because of pressures. (Missouri; Oklahoma; North Carolina; Arizona).	

	REFERENCES
D. Planning for objectives is broadest at the top and becomes narrower in scope and more specific at each subordinate layer. 1. Administrator plans overall program. 2. Field supervisor plans to implement administrator's program as it relates to operations, line or staff function. (Each level is vital to the accomplishment of the end result.) 3. Station supervisor plans routine procedures to meet specific supervision requirement. (Each subordinate level plans to implement or carry on his phase of the overall program.)	
E. Benefits from the use of objectives or goals in planning. 1. There can be no real planning if final objectives are not well identified. 2. Planning is easier and more purposeful when "end product" is identified and attainable. 3. Much unproductive work can be avoided as unrelated goals or unreachable or impractical objectives are eliminated. 4. The goals or objectives of each level of planning are directed toward and in support	Ref. #5, pp. 72-73

20561

	REFERENCES
of the ultimate goal or objective which is a safer highway transportation system.	
a. The success of the PMVI program is based on a fine balancing of proper planning and performance at each level of operations. (See attached drawing depicting this balance.)	
5. The establishment of goals serves in direction and control.	
6. The establishment of goals are important to employee motivation and morale.	
IV. SINGLE USE PLANS (Second type)	Ref. #5, pp. 30-40
A. A course of action to fit a special situation which may be non-recurring, but may be applicable for more than one use.	
B. Uses of single use plans.	
1. Setting up major programs.	
a. Parts of a single use plan of this type may become, in fact, operational policies or procedures, but the plan as a whole is intended only to develop a program. Example: Planning for the adoption of the Diagnostic Center	

PLANNING FOR
The Inspection of Motor Vehicles
The Selection of Programs, Personnel, Equipment, Facilities, Records
The Training of Personnel
The Certification of Personnel--Facilities and Equipment
The Direction & Control of Operations by Station Supervisors
Field Supervision of Operations
Adminis-tration of PMVI
Safer Vehicles Operating on Highways
LEADS TO

20563

	REFERENCES
Inspection concept in major cities. (1) Planner sets up steps or stages by which the goals will be reached. The PERT or Critical Path techniques are useful systems. (2) Timing of each step is identified. (3) Planner attempts to anticipate bottlenecks. (Bottleneck may be the location and cost of training as well as selection or maybe a failure of supplier to provide equipment.) (a) Example: Problem of selecting and training employees, with consideration of salaries to be commanded by skilled personnel needed to operate such equipment. (b) Possible need to develop public understanding and support for the new system. (c) Prepare arguments to counteract political pressures which may be brought to bear.	

20564

	REFERENCES
(d) Anticipate pressures and prepare to deal with them from the present "in" group who are doing inspection.	
b. A proper major single use plan will include plans for coordinating with whatever other organizations or functions are involved:	
(1) Budgetary considerations.	
(2) Record keeping.	
(3) Supervision or administrative problems which may be factors.	
2. A second type of single use plan (planning for projects.)	
a. Not as broad as major plans, but deals with a one-time, non-repetitive program which may call for some special study: such as a study to determine training needs; to analyze the success or failure of a special inspection technique; or to do a cost study on a procedure.	
b. May include planning for special programs. Research activities will often call for	

	REFERENCES
some special information gathering, or setting up control groups, etc.	
3. The third type of single use plan (for detail planning).	
a. Such plans are used when special operations are needed in carrying out portions of a major program. The element of timing of each special operation becomes a factor and detail planning will include the time factors involved in each detail to be carried out.	
(1) Example: In arranging to set up and test a new type of inspection equipment subsequent to purchasing same, or authorizing the equipment's use in the state. Detail planning for each phase of the test and the timing of each phase are important. Considerations in this example are: securing test sites; securing and setting up equipment; conducting test; releasing equipment. (See (b) below).	
b. Can be used in picturing every step in a series of operations which are	

20566

	REFERENCES
contemplated, but which may only be a "one-time" operation. (1) There are limits on this series of steps, based on how well you can predict or forecast future events and the end result of each step in the series. C. Benefits of single use plans. 1. Integrated and purposeful action more readily achieved when total actions are considered in advance. Review of actions anticipated can disclose possible points of conflict, or need for coordination, etc. 2. Crisis and delays can be avoided as planning will reveal weaknesses, and remedies can be applied before the fact rather than after the fact. 3. More efficient and practical methods can be developed, replacing customary or old "we always did it this way" methods, if such replacement proves to be warranted. 4. Delegation of authority and general control of the operation is improved by allocating	

	REFERENCES
time for needed communications. a. Explanation and clarification being made in advance of actual implementation. 5. Such planning provides guidelines for future planning, for as the plan is implemented the weaknesses and/or strengths in planning are revealed. V. THIRD TYPE OF PLAN - Plans for routine operations - often called Standard Operating Procedures (S.O.P.) also include repetitive use plans and plans for emergencies. (A well organized operation will have a set of written procedures for repetitive operations.) A. S.O.P. defined - using the same decision over and over again in guiding actions. 1. Such plans establish uniformity of action where more than one department or section are performing an operation. 2. Establishes a "normal" pattern of action. Planner can then concentrate on only those phases within the plan that need changing as a need develops. 3. S.O.P.'s have essential application in three main areas: (These three to be	

	REFERENCES
discussed more fully in this text.) a. Developing and maintaining policy. b. Establishing and maintaining uniform operating procedures (S.O.P.). c. Ascertaining and prescribing best methods and/or techniques. B. Policies 1. Definition - a general plan of action which guides members of the enterprise in the conduct of its operation. Policies should be designed so that they do not constrict action adversely. They should not be so arbitrary as to leave no room for personal judgment to operate. 2. Policies are needed to: a. Provide uniformity of action. b. Relieve executive or his subordinate from constant decision-making. (1) The danger here is that neither the executive or his subordinate will look for or recognize need for change. May even resent change because of long established use of an S.O.P. or policy.	

20589

	REFERENCES
c. Policy is likened to a highway; the motor vehicle operator has considerable latitude in traveling over the highway toward his objective. The same operator, however, may be restricted by certain basic laws (rules) as to his driving behavior. These rules do not limit the operator from reaching his objective, but they do limit his manner of doing so. Finally, policy states an objective, and this statement of objective should keep the personnel in the PMVI organization aware of the direction which the program should be going to meet that objective.	
C. Standard Operating Procedures (most state manuals on PMVI are made up of S.O.P.'s).	
1. Definition: an approved step-by-step detailed delineation of process in handling or dealing with a certain operation or procedure.	
a. S.O.P.'s are usually spelled out. Generally quite detailed.	
b. An S.O.P. is distinguished from policy or broader planning concept in that the	

	REFERENCES
detailed instructions do limit actions or decisions necessary. (1) In good administration, review of S.O.P.'s are routinely done. In addition, employees are encouraged to analyze and recommend changes. 2. Benefits from S.O.P. a. Should assure that all essential things are accomplished at right time, place, in correct order, in uniform manner. b. Less direct supervision and direction will be needed. c. May have a direct relationship to the amount of training which is needed. (1) Specifics are more clearly set forth. Steps in procedures identified, and end objective stated. d. Speeds up performance by establishing well designed routines which eliminate wasted motions and which employ most efficient procedures.

VI. LIMITATIONS TO PLANNING	
A. It is difficult to plan long-range programs when planner is unable to forecast accurately.	
1. Unanticipated change in vehicle design can negate an otherwise successful plan for carrying on inspection.	
2. Economics can alter budgetary "guesses".	
3. Political changes can make decided changes in programs in some jurisdictions.	
4. Inability to negotiate long-term contracts and leases affect economy of operation. (Some states have very short-term leasing ability.)	
5. A plan is only useful as long as the assumption on which it is based will prevail. (See items above.)	
6. Planner must predict on the basis of sound data, good analysis, consideration of all factors. He may need to propose alternatives when and if certain uncertain variables should occur, such as:	
a. Budget cuts.	
b. Legislated changes.	

	REFERENCES
7. Planner may need to show ways to surmount problem areas for which there is the least degree of predictability.	
B. Planning is limited when there is little repetitive operation. This is not a problem in PMVI, for most operations, once organized, are highly repetitive.	
1. When establishing a procedure for an operation for which there is no past precedent, the planning is based on "best judgment" concepts. Example: In PMVI there might be an added inspection procedure for checking all vital chassis metals for fatigue using some type of advanced radiological instrumentation.	
2. Planner as in case above might have to borrow and/or analyze experiences from some related field. A related field in the case above might be the aircraft industry or the auto racing field.	
3. Being unable to forecast and having no previous experience points up the necessity for testing plans before final adoption.	
C. Status quo is a limitation to planning.	

	REFERENCES
1. Reluctance to change is a psychological factor which permeates most organizations.	
2. Adoption and use of someone else's plans limits planning, too.	
3. The need to meet current demands for service can stifle a plan to increase service or change operations for fear that what is being done will be altered.	
4. Planning requires supervisory and administrative energy. An administrator that is complacent or satisfied with things as they are is not likely to plan to change and/or improve them.	
D. Planning costs money in manpower and time. The improvement in results may not warrant the cost of planning to make the change.	
1. Planner might, as an example, spend many hours in study of inspection station "layouts." He then proposes some minor rearrangement which may not materially affect the quality of the inspection. The cost of the planning would not warrant the time spent considering the benefits received from the change.	

	REFERENCES
2. Cost is not always in money. It may show up in loss of use of equipment, manpower, services, or neglect of other needs.	
E. Time in which to plan is a deterrent to planning.	
1. Planning is time-consuming and organization must budget executive time and money to meet the needs.	
2. Deadlines to be met often do not allow time for planning.	
a. Assume that the legislature decrees that within 90 days the inspection section shall check speedometer calibration, which is a new program. The administrator is limited to planning and implementing a major change in much too little time.	
3. The lack of time calls attention to the need for having advanced planning for "eventualities" whenever there is any forseeable possibility of an emergency (eventuality). This may involve starting preliminary planning once a strong suggestion arises from an authoritative source that some changes may	

	REFERENCES
be "in the wind".	
a. Legislative lobbyist often may give clues.	
b. A legislator's inquiry may give administrator a hint.	
c. Changes in neighboring states may presage a change in the "home" state.	
F. Limitation detailed planning may place on individual initiative.	
1. S.O.P.'s do restrict decision-making on a particular problem. There must be some administrative recognition of need for individual judgment in emergency situations.	
2. Planners should, where practical, get subordinate participation in formulation of plans in order that plan acceptance is better, and to make certain they have all the facts.	
VII. STEPS IN PLANNING	
A. Clarify the problem.	
1. What is anticipated? What is reason for needed change?	
2. What do you expect to accomplish?	

	REFERENCES
B. Determine objective and identify key factors or reasons for selecting procedures designed to meet objectives. Consider alternatives.	
C. Analyze facts, sifting, combining and relating them to problem at hand. The planner at this stage must be critical, often almost negative in thinking, looking for all possible roadblocks.	
D. Decide on action to be taken, giving consideration to others who have an interest or concern in the plan and its operation.	
E. Arrange for execution of the plan. This involves the issuance of administrative orders and the development of time tables for performance.

SUBJECT: DIRECTION - A FUNCTION OF MANAGEMENT

HOURS: 6

OBJECTIVE: To create an understanding of the function of directing and how the proper use of directives can aid in the administering of a motor vehicle inspection program.

METHODS OF INSTRUCTION: The primary method of instruction is lecture, supplemented by classroom projects and discussions. Students should be required to bring a copy of their organization's orders, rules, manuals, etc., which contain directives pertaining to vehicle inspection. This material should form the basis for classroom discussion and projects.

INSTRUCTOR'S GUIDE

(DIRECTION - A FUNCTION OF MANAGEMENT)

I. INTRODUCTION

A. Instruction should provide the student with understanding as to the role direction plays within a periodic motor vehicle inspection program. The student should be made aware that directives may be written or oral and that both types require planning and preparation.

The importance of a system of directives to the coordinated efforts of a vehicle inspection program should be emphasized to the students. It should also be emphasized that written policy which documents the mission and intent of the vehicle inspection agency should be the basis on which directives are formulated. The student should be made aware that directives not only refer to persons employed by the vehicle inspection agency, but also include people who are licensed to operate inspection stations, mechanics who are certified as inspectors, and the vehicle owner who is required to have his vehicle inspected.

Instruction should emphasize the need for uniform inspection procedures throughout the state if the program is to be successful. To accomplish this the administering agency must incorporate procedures which assist in achieving success rather than impede it.

II. PRESENTATION A. What we mean by Direction 1. Directing is the process which is concerned with the way management issues instructions and otherwise indicates what is to be done. It is the continuous task of making decisions and implementing the decision through instructions. This task is extremely important to the success of a vehicle inspection program, for it embodies the function of guiding and controlling efforts, state-wide, toward hoped for goals. a. The term Directive as used in this unit of instruction refers to any and all types of instructions which require action on the part of the person or persons receiving such instructions. Webster's Seventh New Collegiate Dictionary defines Directive as "something that serves to direct, guide, and usually to impel toward an action, attainment or goal; an authoritative instrument issued by a high-level official body or competent official.	

Machines. 7 min., 16 mm., sd., b & w. Contemporary Films, Inc., 267 West 25th Street, New York 10001 or 614 Davis Street, Evanston, Ill. 60201.
Summary: Reconstructs the steps that led to fatal accident caused by carelessness and handling machinery.

Safe in Hand. 20 min., 35 mm. film strip, sd., b & w, 1946. Associated Films, Inc., 347 Madison Avenue, New York 10017.
Summary: How to pick and use right tool safely.

Safety Depends on You. 13½ min., 16 mm., sd., b & w or color, 1959. Public Service Films, Inc., 6626 Romain Street, Hollywood, Calif. 90038.
Summary: Covers all general hand tool safety precautions.

Sharp as a Razor. 15½ min., 16 mm., sd., b & w or color, 1959. Public Service Films, Inc., 6626 Romain Street, Hollywood, Calif. 90038.
Summary: Sharp cutting tools are safe when used properly.

Fire Prevention and Fire Safety

Extinguish that Fire. 25 min., 16 mm., sd., color, 1965. Los Angeles City Fire Department, 217 South Hill Street, Los Angeles, Calif.
Summary: Shows classes of fires and how to handle appropriate types of extinguishers.

Are You Sure. 14½ min., 16 mm., sd., color, 1962. Associated Films, Inc., 347 Madison Avenue, New York 10017 or regional office.
Summary: Fire employees think they caused serious industrial fires. Each reviews his careless acts.

Cause for Alarm. 13 min., 16 mm., sd., b & w, 1950. Associated Films, Inc., 347 Madison Avenue, New York 10017 or regional office.
Summary: What to do in case of fire.

Flammables Engineering. 26½ min., 16 mm., sd., color, 1960. The Protectoseal Company, 1920 South Western Avenue, Chicago 60608.
Summary: Flammable liquids and their use. Also fire prevention principles applied to handling.

Know Your Fire Extinguishers. 20½ min., 16 mm., sd., color, 1950. Factory Mutual Engineering Corporation, 1151 Boston-Providence Turnpike, Norwood, Mass. 02062.

Waterfog, Master of Fire. 37 min., 16 mm., sd., color, Rockwood Sprinkler Company, 38 Harlow Street, Worcester, Mass.
Summary: How waterfog controls flammable liquid and the principle and operation of equipment.

	REFERENCES
2. The vehicle inspection agency should publish an administrative manual. This manual should contain sufficient guidelines and instructions so that each person involved in the program will know what is expected of him and how he is expected to function in his particular job capacity. This manual should be issued to all agency employees with management or supervisory responsibilities. In those jurisdictions where inspections are conducted by state-appointed stations, an appropriate manual should be published and issued to each station and to each certified mechanic-inspector. In those jurisdictions where inspections are conducted by state employees, each employee should be issued a manual. There must be a system of numbering or identifying each item in the manual in order that revisions, deletions and additions can be made easily and correctly. The format of this identifying system is not critical as long as the recipient of the material can identify its purpose and make the proper insertions,	

	REFERENCES
deletions and/or changes of the material into the manual.	
3. Methods of distributing inspection directives and information:	
a. General orders - issued to announce adoption of/or revision of policy; to identify changes in organizational objectives; to set forth responsibilities of the levels of command within the organizational structure. It is not expected that General Orders would be subject to everyday changes, but be of a more permanent nature.	
b. Special orders - issued to announce policies or direct procedures concerning a specific circumstance or event. An example in PMVI could be found in setting up and conducting a special inspection program on a limited area basis to test a new type of equipment (dynamometer, as an example).	
Special orders can also be those that by their nature will not be applicable after	

	REFERENCES
the subject to which they apply is no longer in existence, or needed. Example, in above paragraph, after the test of the dynamometer is completed the special orders no longer apply.	
c. Operational orders - orders designed to give detailed instructions on how to perform specific functions. These orders are found in all state inspection manuals where instructions are set forth for inspection of component parts of motor vehicles.	
d. Personnel orders - are concerned with the personnel function within the vehicle inspection agency. They cover the appointment of new personnel; the assignment or transfer of members from one unit to another; the promotion, demotion, suspension, dismissal and restoration to duty, and termination by resignation or retirement of a member of the organization.	

	REFERENCES
e. Bulletins - may be issued for the following purposes: (1) To disseminate information or instructions which do not warrant a formal order. (2) To direct the actions of subordinates in specific situations or circumstances under a level of command not authorized to issue General or Special Orders. (In motor vehicle inspection a field supervisor may have information which interprets orders for station supervisors; such information may fall in the "bulletin" category. Such information must not deviate from or conflict with established policies and procedures as documented by higher authority.) (3) To inform members of actions or policies of other agencies.	
4. When it becomes necessary to issue a general or special order, responsibility for format and content of the order should be vested in	

	REFERENCES
one of the staff officers of the organization. This responsibility should include the obligation to review previous orders to see that duplications and/or conflicts do not exist. Where practical such orders should be so written as to make them self-cancelling when their use is no longer applicable.	
a. The staff officer assigned this responsibility should maintain master files of all departmental orders. He should review all orders periodically to determine if they still represent management's thinking.	
B. Consideration before issuing Directives	
1. Direction defined:	
a. The essence of direction is assignment. Literally, direction consists of ordering someone to do something; to take an action; to cease an action; or combinations of both. The person ordered to perform may or may not be a subordinate, depending on the type of action which is to be taken.	
Direction in Motor Vehicle Inspection takes place, as an example, when the Administrator of the PMVI program tells his Field	

	REFERENCES
Supervisors to assign more men to field vehicle spot checks; direction is at work when the Field Supervisor orders Station Supervisors to alter station inspection procedures. The same is true when the Station Supervisor advises a mechanic inspector to use a new inspection form. Regardless of the management level which initiates a directive, the initiator needs to make sure that he clearly understands the problem that brought about the need for it. He should then look at alternative procedures available to him and select the procedure that most effectively fits the particular situation.	
2. To be considered is whether or not the directive should be in writing. In arriving at this decision the initiator of the direction or directive must know the policy of his agency as to written and verbal directives. It may well be that agency policy will decide this question for him. If not, the initiator should consider the importance of the matter under consideration. Is the problem that caused the need for	

	REFERENCES
this directive sufficiently important that written documentation may later be needed? Does the expense of putting the directive in writing outweigh the results of what is to be expected? As an example, the cost of writing and distribution of a directive calling for block printing on an inspection form far exceeds any monetary gain which could be expected from such a procedure. Is the person to whom this is directed the type that needs instructions in writing? Is this directive going to be repeated to many people at different times and locations? How complicated and/or technical is the subject matter of this directive? Does it make sense to put this particular directive in writing? These are the type of questions which should be considered when deciding if a directive should be written or oral. a. When deciding if a directive should be written or oral, it should be remembered that the success of a vehicle inspection program depends heavily on the honesty with which it is run and the acceptance of the program by the public. Because of	

	REFERENCES
this, some directives should be in writing so that there can be no doubt as to the meaning contained therein. Also, written directives can be used as part of a public information program aimed at gaining public support for vehicle inspection by documenting the intent, procedures and administrative controls of the overall program.	

C. Characteristics of good directives

1. Directives, to be beneficial to the program, must contribute to making the procedure or policy effective. They must be complete enough to secure and maintain uniformity of action, but at the same time leave room for flexibility. They must seem reasonable to the person who is to carry out the direction. Considerations here are:

   a. Do the personnel involved here have the necessary ability and experience to carry it out? For example, it would be ridiculous to direct station supervisors to test headlight aiming equipment without first providing them the necessary

	REFERENCES
training on how to conduct the testing.	
b. Do we have the necessary facilities and equipment to carry the directive out? This might be a consideration when deciding upon the type of an inspection program to be conducted and whether vehicles are to be inspected annually, semi-annually, etc.	
c. Can the quality of performance desired be achieved within the time stated? For example, in determining how frequently inspection stations will be contacted by station supervisors, the administrator must consider the number of stations to be inspected, the length of time needed per station, and their geographical dispersion.	
2. A directive must be clear and understandable to the person receiving it. To satisfy this characteristic, the initiator should place himself in the position of the person receiving the directive to see what questions he would ask about it.	

	REFERENCES
a. If directives are written covering a complicated process, the administrator may consider first developing a sampling procedure in which a limited number of persons receive the directive. This group of persons then "live" with it to determine whether or not it meets the administrators proposed objectives for it. Constructive comments from this trial run can then be incorporated in the official directive which then is distributed throughout the organization.	
3. The system through which directives flow should be designed so that the new directive starts at the highest affected level within the vehicle inspection agency and moves down the organizational heirarchy by level. In this manner each level becomes aware of the content of the directive prior to the next subordinate level. This should provide each lev el the opportunity to understand the intent and the "why" of a directive in order to be able to properly explain it to the next group in the organization. This system should result in field and station supervisors being

	REFERENCES
better able to clarify directives to state-appointed personnel when the directive affects their operations. A system such as this should result in directives being implemented in the field with the same intent with which they were published.	
D. Follow-up as a technique in Direction	
1. In order for directives to achieve their purpose, supervisors must, on a continuing basis, visit with those levels in the inspection program who have the responsibility for implementation. These visits are necessary to make sure that directions are being followed and that operations are being conducted in the manner and within the time desired. This does not mean that such inspections are only for the purpose of discovering persons who are willfully winking at requirements of the directives but, rather, that supervisors are constantly checking to make sure that the contents of directives are understandable and realistic.	
2. The importance of follow-up as a technique in direction is emphasized in motor vehicle	

	REFERENCES
inspection programs by the wide decentralization of operation levels of personnel involved. In state-owned operations, directives must be channeled to appropriate offices and locations in order to keep programs progressing forward. When one realizes that these programs have to do with such varied functions as personnel, finances, and the inspecting of vehicles, the importance of clear, understandable and reasonable instructions, arriving in time to be implemented on schedule, is better understood. a. In state-appointed programs the above is still true, but now personnel not employed by the state become involved. They usually are less knowledgeable in the vehicle inspection agency's terminology and internal requirements, and need closer supervision to ensure their proper compliance with the intent of directives. However, it is not unusual for these same non-agency people to be the source of intelligent suggestions which can lend to the efficiency of vehicle inspection. They, along with all recipients of directives, should be allowed an avenue of	

	REFERENCES
communication to accommodate feedback information connected with program operations. The follow-up visits of supervisors should and could supply this channel of communications.	
3. Follow-up can assist in another important element of good direction. This is the need to countermand directives which are no longer in force. In those systems which are designed to be self-cancelling it would be nice if all the users of the directives would recognize that the directive is no longer in force and cease to use it. Practical experience indicates that this doesn't happen and follow-up is necessary. This is particularly important in vehicle inspection programs where administrative rules often carry the weight of law. It emphasizes the importance of the vehicle inspection agency keeping abreast of the state statutes that control, or allow its operation, so that directives issued by the agency comply with legal requirements.	

20594

	REFERENCES
E. The Use of Standard Operating Procedures 1. Standard Operating Procedures are used for operations which are repetitive in nature. Once they are properly set up the task of directing is eased. A good supervisor, at whatever level he may be, will create a set of attitudes that will lead subordinates to perform in the manner he desires. The natural conclusions, if the above is true, is that the more standard operating procedures you have, the less direction you'll need to exercise. Some operations within vehicle inspection programs which could be guided by standard operating procedures are: a. The requesting of inspection stickers by using stations, and the issuing of them by the governing agency. b. The periodic inspections of station facilities and mechanics by station supervisors. c. The inspection of a vehicle by the mechanic-inspector. d. The handling of complaints from motorists concerning operations of an inspection facility.	

20595

	REFERENCES
F. The Function of Training in Direction	
1. The training program of the vehicle inspection agency should be based, in part, on the departments directives and standard operating procedures. The training personnel can direct their teaching activities toward developing a student understanding of the departments policies, its standard operating procedures and other departmental guidelines which are used in directing the organization's functions. A thorough understanding of the wishes of management assist in the student's learning and performing his job. When this learning takes place it is simpler to direct activities, for the subordinate knows more about his task.	
2. All training does not take place at the agency's training school. The many changes taking place within the vehicle inspection field suggests that training should be a continuing function. Therefore, some portion of training will take place in the field away from the training school environment. Under these conditions there is an evident need for good supervision and supervisors in seeing that "in the field" training continues.	

20596

	REFERENCES
Because of the decentralized nature of the motor vehicle inspection operation, much of the updating of personnel will take place away from the training academy. In the field training supplements the formalized academy training and aids management in directing the organization's operation.	
3. Direction of persons not in the employ of the state motor vehicle inspection agency is aided by the development of training for such persons. In the state appointed inspection systems the operational type employee, i.e., the mechanic-inspector, is not subject to the direct orders of the state's official station supervisor. The mechanic-inspector must, therefore, be regulated by specific rules but in addition, he can be motivated and educated by proper training.	
a. When talking about the "why" of directives, it is proper to once more mention state-appointed operations and the fact that many persons involved in vehicle inspection programs are not employed by the vehicle inspection agency. These	

	REFERENCES
people are the ones who talk with the public and who are in a position to further the aims of vehicle inspection and highway safety.	
b. A subject area which should not be overlooked when explaining "why" is the changes which have been brought about by the National Highway Safety Bureau through its standards, particularly the one dealing with PMVI. The reason for recording of the odometer reading, for example, is one item of explanation which could be given to these people so that they could be prepared to tell the public to what use this information is to be put within the overall highway safety program.	
G. The Use of Consultation in Direction	
1. When appropriate and practical, those people who will be responsible for the execution of a directive should be consulted about it. These people usually are in the best position to know if a proposed directive is workable, reasonable, or even needed. Often times they	

	REFERENCES
can suggest alternate means which accomplish the same ends, but much easier and perhaps less expensively. This advice and counsel should not include only agency personnel but should take into consideration inspection station personnel who may actually be the ones that will have to perform the function described in the directive.	
2. The method of consultation, when used in a motor vehicle inspection agency, may vary according to the urgency and/or complexity of the subject. The telephone, a letter, a questionnaire, or a staff conference may be used. Regardless of the method used, there are benefits to be had in discussions before directives are formulated. Some of these benefits are:	
a. The performance of employees is improved when they have had the opportunity to be heard or to aid you in deciding what or how a job is to be done.	
b. The directive - finally adopted - will have the benefit of the thinking of a number of people and may well be better	

	REFERENCES
suited to the task than one which was developed by only considering the opinions of one person.	
c. Better understanding of why the directive is needed and the steps needed to implement it will occur at all levels of execution.	
H. Briefings as a Part of Direction	
1. Once a directive has been decided upon, supervisors often hold briefings in order to explain the directive to subordinates. This occurs throughout the chain-of-command and will often end when the station supervisor briefs station owners and mechanic-inspectors. Briefings are useful in direction for they give the person doing the briefing a chance to sell the reason behind a particular directive. If the directive results in a person having to do more work to accomplish what appears to him to be the same end, a briefing should clarify this and explain the change in procedure. An example of this would be when a vehicle inspection agency adopts electronic data processing	

	REFERENCES
techniques with the resultant change in forms which are filled out by the mechanics when inspecting vehicles. At first the new forms and procedures may seem overly time-consuming, but once the complete procedure is explained the mechanic should better understand what is being done, and why.	
2. In order to be effective the person conducting a briefing should be aware of some requirements for them to be a success.	
a. It is necessary to analyze the briefing. To whom is it going to be presented? What do they actually have to know? Where is the briefing to be given? Why was it decided to hold a briefing on this particular directive? These are all questions which should be answered before the start of the session.	
b. Preparation for the briefing is necessary if you expect the listener to take it seriously. The speaker should prepare an easy to follow outline of what he wants to get across. He should have sufficient graphic material to emphasize points he

2035

	REFERENCES
is going to make, but not so much material that he will overwhelm the listeners. He should rehearse his presentation so that it will be effective.	
c. When making his presentation he should make sure he identifies himself, if there are those present who have never met him. The purpose of the briefing should be explained and when he has completed his presentation he should answer legitimate questions. If he doesn't know the answer to a question, he should say so. If he knows the answer, but for some reason cannot divulge it, he should say so.	
I. Policy in Direction	
1. Policy is a "code" by which all people in an organization are guided in making decisions and in taking action in a given situation.	Ref. #2, pp. 40, 42, 108
It identifies the direction action should take. Policy provides a common guideline to enhance uniformity of action. It displays what the administrator stands for and what he wants his organization to accomplish. Policy	Ref. #1, Sec. 4

	REFERENCES
stipulates the objectives in the broadest sense. The authority to take action presupposes that the doer will function within the boundaries of the policy. Policy, being broad, encourages thinking and permits discretion on the part of subordinates.	
2. A rule differs from policy. A rule is a prescribed guide for conduct. It is not nearly as flexible as policy. Rules usually leave no latitude for decision-making. They describe who is to act, when, how much, and exactly how.	
3. Policy must conform to statutes, economic principles, governmental operating restrictions, and must be compatible with the public interest. In order to avoid misunderstandings, the policy of the vehicle inspection agency should be reduced to writing. This allows all to know the aims of the program and of the vehicle inspection agency itself. It also results in more effective direction, for all employees of the inspection agency must know the boundaries within which they operate.	

20603

	REFERENCES
J. Conclusion 1. The management of the vehicle inspection agency can, through the proper use of directives, develop a set of beliefs and attitudes beneficial to the success of agency programs. Some basic concepts around which the agency is built and functions, and which directives help promote, deal with: a. Ethics: This is extremely important to vehicle inspection because every vehicle owner is being forced to do something that he might not otherwise have done - get his vehicle inspected. He has to be convinced that the program and its administration is completely honest. b. Loyalty: Loyalty to management and the organization is a management objective. Directives show employees and others for what and on what the organization stands. Directives should form a basis for employees and state-appointed personnel to want to be loyal to the organization and its objectives.	

20604

	REFERENCES
c. Public Relations: Directives should leave nothing to the imagination as to the importance of each contact between a vehicle inspection agency employee and the public whom that employee serves. These directives should not omit station owners and mechanics in the state-appointed operations.	
2. Management's attitudes should filter down through the organization. All personnel connected with the program should sense the principles under which the agency operates.

SUBJECT: DELEGATION - A FUNCTION OF MANAGEMENT

HOURS: 6

OBJECTIVE: To improve the student's ability to direct activities in administering a Periodic Motor Vehicle Inspection Program by acquainting him with the processes of delegation.

To provide the student with substantive knowledge of the process of delegation in order that he can recognize the need for applying sound delegation principles.

METHODS OF INSTRUCTION: The principal method of instruction is a lecture presentation. Supplemental reading in the area of management principles may be assigned. Recommended readings are:

1. Albers, Henry H., Principles of Management, third edition, John H. Wiley & Sons, Inc., New York 1969

2. Hutchinson, John G., Organization: Theory and Classical Concepts, Holt, Rinehart and Winston, Chicago 1967

3. Koontz, Harold and O'Donnell, Cyril, Principles of Management, third edition, McGraw-Hill Book Company, New York 1964

The instructor may present an organization chart depicting the placement of the PMVI function within the structure state government. A second chart, or a continuation of the first may then be used to show how the organizational structure tends to establish areas of responsibility, span of control and chain of command. Sample organizational

charts can be found in the unit of instruction on "Introduction to Organization."

In this subject area the role of the staff officer should be stressed, with emphasis placed on the staff officer as an aide to the administrator and who acts, not for himself, but for the administrator.

The fine line between staff counselling of a subordinate, not under his direct command, and staff directing that same subordinate contrary to the dual subordination principle should be identified.

Project work in this area can best be done after the student has studied Direction and Policy. Once this is accomplished the student should be ready to play the role of management in delegating tasks. This can be done in written form with the requirement that the limits of authority and objectives of the assignment will be identified.

Suggested areas of assignment for project work may include: Writing Policy; Issuing Orders; and Delegating Authority to subordinates for:

1. Developing and implementing a records system.
2. Adding additional components to the inspection system.
3. Preparing new inspection manual.
4. Defining levels of authority and responsibility within the PMVI section and showing how the PMVI section relates to the organizational structure of motor vehicle administration.

INSTRUCTOR'S GUIDE

(DELEGATION - A FUNCTION OF MANAGEMENT)

I. INTRODUCTION

A. Purpose of this session

1. In management many administrators are unwilling to free themselves of tasks which should and could be done by subordinates. The administrator burdens himself with so many jobs that he does not have time for tasks which only he can accomplish.

The purpose of this subject is to have the student:

a. Recognize the need for delegation.

b. Understand the relationship between authority-responsibility and accountability.

c. Comprehend how an administrator builds and molds his organization by delegating to responsible subordinates those tasks which they can perform and which permit them to develop administrative skills in their own right.

d. Be aware of the problems of dual subordination and how dual subordination can adversely affect line supervision.

e. See the value of manuals, policy and rules in delegation, particularly as these devices aid in establishing limits of authority, clarify organizational responsibility and help in resolving jurisdictional problems.

II. PRESENTATION - (Delegation as a tool of management) Introductory Remarks: Delegation takes place, even in the smallest organization. Administrative organization creates the executive-subordinate relationship. The executive delegates the authority for subordinates to perform portions of the organizations function. The delegation of authority creates a responsibility on those authorized to perform. An unwillingness to delegate is a serious problem for an executive.	Ref. #4, p. 183
A. Definition of Authority	Ref. #4, pp. 180-183
1. As used in the context of this lecture, it does not refer to legal or technical authority, although this is important to PMVI administration.	
a. Legal authority is that given by law.	
b. Technical authority is that authority which is derived from expertise in specialized fields of endeavor.	
c. In public administration and, therefore, in PMVI, the ULTIMATE authority rests with the people.	

	REFERENCES
2. In our discussions we are referring to <u>operational authority</u>. a. Operational authority means that someone is authorized or permitted to perform certain acts. b. Accompanying the delegation of operational authority is or should be an indication of how that authority is to be used and the limitations on same. As an example: The Administrator delegates to a subordinate the task of evaluating a new type of testing device. He is told to perform exhaustive tests to determine whether or not the device will improve the inspection of motor vehicles. At the same time, he is instructed to analyze the cost of the instrument or instruments and if his report is favorable, to do the necessary staff work to set up the necessary procedures for purchasing such equipment. A limitation is placed on him, however, in that he is advised: (1) not to proceed with

purchase until administration approval is had; (2) not to give any indication to the equipment supplier as to his decision as to the feasibility of adopting the equipment; (3) to report the results of his work.	
B. The Nature of Delegation	
1. Delegation exists in any organization where there is more than one employee.	
a. It takes place when one man takes a helper.	
b. Delegation does not relieve the delegator of his ultimate responsibility for the function.	
c. Delegation requires risk-taking. The risks are these:	
(1) The delegator permits the subordinate to exercise judgment on how to proceed. The risk in this delegation is that the subordinate may misconstrue the intent and "take off on a tangent". (Good management calls for the administrator	

	REFERENCES
to be sure the subordinate knows what is wanted and the general guidelines for proceeding).	
(2) There is a risk too that where exacting limitations are placed on the subordinate he will not accomplish the task in as competent a manner as he would have if he had been permitted wider latitude of power to make decisions.	
(3) The administrator must, therefore, be aware of the risks, weigh them, know his personnel and then be willing to accept their actions.	
C. Three Aspects of Delegation	Ref. #4, p. 186
1. The assignment of duties by an administrator to his immediate subordinates:	
a. Who does what and who eventually performs the operation may require further delegation, down the line. In organizational structure this redelegation or assignment of duties may stop only at the lowest level of operations within the organization.	

	REFERENCES
2. AUTHORITY must be granted to take such actions as are delegated. a. Authority is defined as power to influence, to command, to perform or to require performance. b. Delegating responsibility without giving commensurate authority is ineffective management. 3. Delegation creates an obligation or responsibility on the part of the subordinate for satisfactory performance of the duty delegated. D. Establishing the Limits of Authority Delegated 1. A failure to clearly define limitations of authority causes vagueness of authority. Administrator may "fall back" on the "but that is not what I meant" technique. a. For example: It is extremely important for an inspection station supervisor to clearly understand the nature and extent of his authority in taking action for violations of the inspection station rules.	

	REFERENCES
2. Policy defines the broad limits within which operations take place; procedures are more explicit. The limits must not be vague. It is the responsibility of the delegator to make the general limits of desired performance (behavior) clear. a. An analogy exists between policy and procedure and a football game. The football field (policy) represents the area of performance. The quarterback is permitted a latitude in judgment in running plays in order to reach the goal line. He can do so as long as he keeps his team moving forward within the boundary lines of the field. The plays he calls (procedures) determine whether or not he accomplishes his objective. 3. Where delegation is a constant process in an organization, the organizational chart and/or the organizational structure establishes limits of authority. 4. There are some inherent limits on authority	

	REFERENCES
over employees. a. In PMVI departmental policies and rules establish certain limits. b. State statutes and civil service rules stipulate others. c. Organizational structure dictates others. d. In actual practice the only authority held by the executive is that which his subordinates are willing for him to exercise. (1) Subordinates can defeat him, unless he removes them or finds means to remotivate them. (2) Some authority is accomplished by negotiation and/or inducements within the organization. Authority to issue instructions can be delegated. If employee objects to instructions he can: (a) Resign - as the most drastic step. (b) Go through the motions of complying but accomplish little.	

	REFERENCES
(c) Be induced through proper personnel relations, supervision and training to follow instructions.	
(d) Employee willingness to comply falls within his zone of acceptance.	
e. The authority to deal with people or processes outside the enterprise must be clearly defined in the process of delegation.	Ref. #2, Sec. 4.4.4
(1) Liaison lines with other agencies within the government often grow unofficially. Eventually differences may arise which can only be corrected through "top-level" intervention. Such intervention may break the Delegation-Authority-Responsibility processes, for it may be necessary for the "top-level" authority to take actions countermanding some orders given by a subordinate who supposedly had authority to issue such orders	

	REFERENCES
but who has exceeded the limits of his authority. This may arise as the result of a lack of a clear definition of the limits of authority.	
(2) In PMVI liaison occurs in many areas:	
(a) Enforcement, records, licensing, accident statistic compilation, etc.	
(b) Outside the governmental area in motor vehicle equipment and accessory supplies, safety organizations, etc.	
E. Principles of Delegation of Authority	
1. There must be a real desire to delegate.	
a. The "boss" that is swamped with work eventually finds he must delegate. If he is uncertain of subordinates, or of himself, he attempts then to regulate too strongly and thusly fails to grant authority to perform. In effect he hasn't delegated.	

	REFERENCES
2. Care must be taken that not too much authority is delegated. a. The administrator must retain for himself the elements of control. b. If complete authority is handed down, the administrator may find he is simply rubber-stamping efforts of subordinates, or even worse, having them "second guess" what he wants done.	Ref. #5, - All
3. Responsibility cannot be delegated, but when delegation takes place there is created a responsibility on the part of the person receiving delegation to perform. (Delegation creates responsibility to the recipient of the delegation). a. In all organizations the responsibility for a function and the resultant accountability lies ultimately with the administrator. b. As the administrator delegates he creates responsibility and accountability for his subordinates. The subordinate then has the responsibility with commensurate	

	REFERENCES
authority to perform, and an obligation of accounting for his performance.	
4. Dual subordination should be avoided.	
a. Employee cannot serve two masters well.	
(1) In PMVI where decentralization occurs, there is a firm need for the maintaining of the "chain of command" in order that a station supervisor is not held directly accountable to two, three, or four levels of command.	
(2) Where dual subordination occurs, employee will tend to set his behavior to please the higher echelons of command.	
(3) In state licensed PMVI the inspection-mechanic may be subjected to a dual role when a PMVI station supervisor conducts a review of his operation. In cases of this kind the inspection-mechanic is in a position of being subject to	

	REFERENCES
the orders of his employer and at the same time may find he is being directed to perform differently by the PMVI station supervisor, for whom he does not work.	
(4) Within PMVI the dual subordination situation can lead to morale problems when a conflict arises between directives from two sources which do not agree, and employee is uncertain as to what to do.	Ref. #4, pp. 191-192
b. Staff activity, properly used, does not need to result in dual subordination.	
(1) Staff man, acting for the administrator, may inspect, counsel and review operations of persons not under his control.	
(2) He must not, except in emergencies, direct the activities, nor issue orders to persons not under his control. He can only do this

72037

	REFERENCES
through that subordinate's line operation or chain of command. This assures that dual subordination does not occur and that the subordinate's superiors are in control and aware of "what is going on." (a) As an example of an "emergency situation" - a staff officer might be obligated to countermand an order of a station supervisor to a station operator when it was obvious that the station supervisor's order was contrary to established procedures and was going to produce difficulties for the station operator. In the event such an emergency arises the staff officer must immediately notify the station supervisor and his superiors of his, the staff officer's, actions and the reason for them.	

	REFERENCES
(3) In PMVI, which by its nature is a decentralized operation, it is difficult for a headquarters staff man to visit a field area without observing some operation which is not going according to procedure. The lower management procedures involve noting the deficiency and the probable causes for same. The staff man can then arrange for corrective action through channels. The staff officer must exercise caution in that a subordinate must not be allowed to believe that an improper inspection technique is correct, simply because a staff officer observed it and did not take corrective action. A simple procedure for alerting subordinate to an improper operation is to open the operation to review and discussion with the subordinate, with the staff officer indicating and/or producing the correct information. This, then, is followed	

	REFERENCES
up with a review of the operation with the subordinate's superiors.	
c. Direct contacts between the PMVI executive and the lower ranks, i.e., persons at a level who normally do not report directly to the PMVI executive, does not need to lead to dual subordination; if the executive is careful not to issue orders to that person directly.	
If the executive has orders for subordinates at the second level below him, he should relay the instructions down the chain of command. He can communicate at these levels primarily to learn and get a "first hand" view of the operation.	
(1) By-passing down the line, i.e., by-passing a level of command, may make an employee indifferent to the wishes of his superior. This can seriously weaken that superior's control over line operations.	

	REFERENCES
(2) By-passing also allows by-passed superior the opportunity to deny responsibility as he was unaware of orders handed down past him.	
5. Authority must equal responsibility in delegation. (If a responsibility is created by delegation then there must be also granted adequate authority to meet that responsibility.)	
a. A subordinate cannot be held accountable for results unless he is permitted to guide activity according to his best judgment. If his best judgment is not adequate this is a risk the delegator must face. If the delegator is aware of the subordinates inability to perform then he must take other measures to get the task accomplished. This may take the form of replacing the subordinate. Such a measure is harsh and can create a morale problem if the administrator does not exercise restraint in acting. (The makings of a supervisor or administrator are founded in this statement.) In PMVI the widespread area of operation necessitates a wider latitude of authority	

	REFERENCES
Identify Relationships Further Through Organizational Structure Charts. (See unit on Introduction to Organization, for Charts).	
1. Position descriptions.	Ref. #2, Sec. 3.6.1 Ref. #3 - All Ref. #4, pp. 302-305
a. Quite often are short and denote the lines of authority with main duties of the position described.	
2. Job descriptions.	Ref. #1 - All
a. A broader view of what employee must do, his area of responsibility, etc.	
b. Should define essential requirements of job.	
c. Should be prepared for each level of management, and for each key group or groups of similar jobs.	
d. Specifications should clearly define:	
(1) Functions of job	
(2) Objectives	
(3) Responsibilities	
(4) Relationship to other job	

	REFERENCES
(5) Limits of authority	
(6) Jurisdiction, if applicable	
(a) Territorial, legal, etc.	
e. The job specs or description should then serve as basis for:	
(1) Training	
(2) Merit ratings	
(3) Salary evaluation	
(The more clearly the lines of responsibility are set forth the better delegation can work. The process of describing jobs and positions in advance cuts down on the necessity for added comments and orders when delegation takes place).	
3. Advantages of a formalized description of the organization.	
a. The executive usually prepares the description and establishes his organization accordingly. (This requires analysis of the organization and can lead to improvement.)	

20628

	REFERENCES
b. Unclear lines of authority can be cleared up.	
c. Overlapping interest and areas of responsibility become more clearly defined.	
d. S.O.P.'s (Standard Operating Procedures) may be agreed upon.	
e. Major duties and responsibilities are emphasized.	
f. Needs for change should be more evident.	
g. A broad overview of the operation materializes which leads to further analysis and possible repositioning, reorganization, etc.	
4. Some limitations to using fully finalized statements of descriptions:	
a. Difficult to draft to cover all needs, and once drafted hard to revise.	
b. The more detailed it is the more frequent changes may be needed.	

	REFERENCES
c. Where descriptions are extensive frictions may be created as employees begin to think "this is not my job", etc.	
d. Charts tend to over simplify relationships.	
e. Inflexibility develops and when changes are made it is often difficult to get acceptance of the changes.

The national standards body in the United States. Prime purpose is to provide the machinery for an orderly and voluntary method of establishing recognized United States of America Standards. Standards are generally accepted as minimum requirements by safety engineers.

2038

SUBJECT: CONTROL - A FUNCTION OF MANAGEMENT

HOURS: 3

OBJECTIVE: To develop student managerial skill by identifying specific administrative devices and tactics used to control the operations of an organization. To improve student's understanding of how control techniques are an integral part of the total management process.

METHODS OF INSTRUCTION: A lecture presentation. The instructor may set up a hypothetical PMVI organization or use an example of an existing program. Have students identify the control factors that are being used or that could be used in the operation. A sample organizational structure chart appears in Volume 1, Highway Safety Program Manual, "Periodic Motor Vehicle Inspection."

INSTRUCTOR'S GUIDE

(CONTROL - A FUNCTION OF MANAGEMENT)

I. INTRODUCTION

A. Control is a major function of good management. The essence of control involves the establishment of criteria for performance and the setting up of "listening" or observational posts along the operational path in such a way that management can determine whether operations are going according to schedule. The post or control also will inform management whether or not operations are following acceptable procedures and accomplishing desired results. The overall purpose of Control being to see that objectives are being met efficiently and on time.

In this session the student should discover how important it is to design and/or build into the operational system control points and techniques which permit managment to evaluate and direct activities which are on-going.

In management, Control is a consideration in Direction, Delegation and Budgeting. The student should become aware of this as he progresses in the management area.

	REFERENCES
II. PRESENTATION	
A. Introduction: Administration has been defined as a continuing cycle of Planning, Organizing, Assembling Resources, Supervising and Controlling.	Ref. #3, pp. 419-466
1. Directing and Controlling are identified as major categories of administrative or managerial work.	
2. Control consists in seeing that all operations are carried out in accordance with the plans which have been adopted and the orders which have been issued. It further consists of determining if planned objectives are being met.	
a. A PMVI organization must develop and adopt <u>controls</u> to help assure compliance with departmental programs designed to accomplish its objectives.	
b. Control mechanisms must function within an organization to protect it from its own elements. The administrator must discover and eliminate individual and group conduct which hampers the organization from successfully completing its programs and meeting its objectives.	

	REFERENCES
Within the organization the competition for personal recognition, for personnel and the budget dollar, necessitates administrative control.	
c. Whenever authority is delegated, some form of control must be initiated to determine if authority is properly exercised.	Ref. #2, Sec. 5.4.3
B. Control as a basic process	
1. Control is an essential and basic process and is an integral part of other activities of management. (Particularly is this true of Direction and Delegation.) For controls to function there must be:	
a. Objectives and goals clearly outlined and understood. (Where you are headed must be known, in order that control techniques can determine if you are actually going that way.) The objective of the control method should be defined. An example of a statement of objectives for motor vehicle inspection is found in Chapter 1, Paragraph 3 of Volume 1, Motor Vehicle Inspection	

	REFERENCES
of the National Highway Safety Bureau.	
b. Procedures for installing control methods and assurances that the procedures will be used.	
c. Appraisals of performance. The principal objective of PMVI is assuring safe vehicles on the roadways of the state. The measure of the success of the program is the quality of the work being done. As a control measure the administrator must regularly test the quality of the inspections being performed. This testing is routinely done by that station supervisor's visits and inspection of the inspecting stations. The unscheduled stopping and checking of vehicles in roadchecks will also give the administrator a test of the performance of his program.	Ref. #2, Sec. 5.4.2
d. Corrective action which originates when control techniques disclose deviation from desired results. (Control techniques which disclose irregularities but which do not prompt remedial action	Ref. #2, Sec. 5.4.1

	REFERENCES
are useless. By the same token, where superior performance is disclosed the control technique should allow for recognition and subsequent improvement in operation.)	
2. The feed-back process provides the administrator with another means for determining whether or not the program objectives and criteria are being met.	
a. Feed-back in motor vehicle inspection is found, in part, through routine reports that are designed to show how many vehicles are being inspected, and their condition. Since the implicit purpose of PMVI is to improve the mechanical condition of vehicles, a study of trends in vehicle defects, i.e., either upward or downward, would indicate whether or not the inspection program is, in fact, improving the mechanical condition of vehicles on the road.	
Some unofficial feed-back comes to the administrator through sources not directly related to reports within the	

	REFERENCES
PMVI records system. The administrator gets a "reading" on how things are doing by reading the complaints received; by noting letters of commendation and/or condemnation; by news media interest and reaction to the program; by the activities of organized groups within the state that have an interest in motor vehicle inspection, such as the Auto Dealers Association; the Automobile Association; Safety Councils, etc.	
3. Types of Control	
a. Organizational structure is designed to provide "span of control" and chain of command.	
b. Staff and line units assume responsibility for and control of functional activities. Position descriptions as found in a number of state personnel operations describe the functional control by staff. Oklahoma has, in part, the following in their position descriptions for motor vehicle inspection personnel.	

	REFERENCES
(1) Director - will be responsible for all operations of the motor vehicle inspection division. He will serve as liaison officer with (independent organization). He will work closely with (other branches of state government). He will conduct all hearings in regard to violations of inspection laws.	
(2) Assistant Director - will be in charge of records, training of troop inspectors, training of mechanics. He will see that all complaints are investigated, be in charge of all office personnel. He will check all reports and will select random samples of inspection station reports for proper evaluation.	
(3) The field supervisor's and trooper inspector's responsibilities are similarly set forth.	
(4) In the above examples in Oklahoma, the administrator has set forth	

	REFERENCES
the areas of performance for his subordinates. Such descriptions provide control by defining areas of responsibility and along with proper reporting procedures should provide the administrator with feed-back on the functions which fall within the scope of activity of the subordinates.	
c. Records and reports are designed and used to provide the administrator with information. Statistical summaries, daily reports of activity, unusual activity reporting, and many other such reports are used to provide information on objective accomplishments and the status of the operations as of the reporting time ... feed-back, in other words.	
d. Staff conferences often are used to gather information. They are also used in directing an organization's activity.	
(1) During staff conferences the administrator can and will determine	

	REFERENCES
whether certain objectives are being met. He can inquire in great detail as to why or why not programs are functioning. Such inquiry constitutes a form of control.	
e. Controls are exercised by the appointment and removal of staff (while this seems drastic, the inability or failure of a subordinate to perform causes a breakdown in operations and removal of the offender may be the answer. For morale reasons, the administrator should consider alternatives to removal). The addition of an assistant may be warranted.	Ref. #3, p. 200
f. Departmental policies and rules provide guidelines for performance. They set standards by which the administrator can determine whether the expected performance is being met. These policies and rules then are the criteria against which the administrator weighs performance procedures of his subordinates. They become, in the control process, an evaluating tool.

Acknowledgment of Safety Instruction and Pledge

I have received the SAFETY INSTRUCTIONS regarding the operation of the following power driven machines. I fully understand the importance of these rules and regulations and I am fully aware that the violation of any one of them may endanger myself and others.

My teacher has demonstrated to me the proper methods of using each machine listed below and has pointed out the safety precautions necessary to avoid injury.

I have demonstrated my ability to use each machine listed below in the presence of my teacher. I understand the safety precautions involved and understand how to insure my safety through the proper use of the machines. I am confident that I can operate these machines safely. When in doubt about the operation of any machine, or other equipment, I will consult the teacher before proceeding.

(Name of each machine to be written in *by the pupil* only after he has passed the safety tests and demonstrated his ability to use it.)

Name of Machine	Date	Student's Signature	Teacher's Initials
1			
2			
3			
4			
5			
6			

I have passed the tests covering safety in the shop and the use of the above listed machines.

I promise to observe the SAFETY INSTRUCTIONS and to follow the instructions given in the demonstration. I may use the machines only after I have been properly instructed in their safe use, and have had the approval of the teacher. I understand that the use of machines in this shop is voluntary on my part.

MICROCOPY RESOLUTION TEST CHART

NATIONAL BUREAU OF STANDARDS-1963-A

	REFERENCES
g. Control is exercised through adequate field and station supervision. The use of random inspection of motor vehicles in a broad sampling basis can disclose the quality of inspections and provide clues to management as to how well inspecting stations are complying with departmental guidelines.	Ref. #1, p. 32
h. Standard Operating Procedures provide concise guidelines. These guidelines establish criteria for performance and here, as in Section f above, the administrator has a tool for exercising control. In motor vehicle inspection the instructions for conducting component parts inspection set forth procedures and end results desired. A failure on the part of an inspector-mechanic to carry out the correct procedures or to correct a defect, when observed by a station supervisor, provides that supervisor with a control measure in that the inspection is not meeting its	

292

	REFERENCES
objective and the reason why not is disclosed.	
C. Methods by which a PMVI administrator controls	
1. Control over personnel	Ref. #1, p. 9
a. Through the recruitment and selection process.	
(1) This area of control is often affected by civil service regulations, state personnel regulations, and political ramifications.	
b. By the placement and transfer of personnel.	
c. Through training.	
d. By promotions and demotions. (The promotional processes and demotional processes of a state civil service system have a material effect on the administrator's control.)	
e. By use of disciplinary authority.	Ref. #3, p. 400
2. Control over records and control through records system.	
a. Control is the backbone of a vehicle inspection program. If the administrator	

	REFERENCES
is to maintain the public trust he must see that the inspection function is correctly carried out. (The records system must be designed to provide feed-back on performance.) R. M. Terry identifies some reports which aid control in his paper, "An Overview of a Successful Motor Vehicle Inspection Program," which is in the unit "Introduction to Organization." These reports are, in part, records on active stations and inactive stations; those stations that are suspended or rejected; records on inspection stickers issued for strict fiscal control as well as subsequent checks on mis-use of the inspection sticker; summaries of inspections for required statistical information as well as indicators of trends. Records on expenditures, records on mechanic training and retraining are maintained.	Ref. #4, pp. 17-20
b. By properly placing the records system within the organization.	

	REFERENCES
c. By establishing accountability for critical report and/or accounting forms. (Numbering of forms, etc.)	
d. By the development of follow-up procedures.	
e. By form design - what information to be reported.	
f. By development of a records flow system and processing system which allows for interpretation of operations at key points. (Management by exception can be mentioned here.) In this concept the records reveal an unusual pattern which is not the norm. When such a pattern is disclosed by the record system, management is immediately advised of the abnormal situation and corrective actions are started. An example of this principle might be found in PMVI when the records indicate that in a given area there is a sudden decrease in vehicle rejections. Such a decrease should alert management to look for the reasons,	

20645

	REFERENCES
3. Financial controls	
a. Budgetary controls - the comparison of use of budgetary items versus the predicted usage identifies deviation from planned progress. An example of this type of budgetary control can be found in the PMVI departmental automotive cost. An overdrawn account in departmental vehicle repair and replacement account provides the administrator with information on trends. One; vehicle costs are going up more rapidly than anticipated; two; there may be vehicle operating policies needing review; three; the demands of the service are creating excessive travel and there may be need for a general review of manpower assignment and/or need for increased personnel.	Ref. #3, pp. 441-455
b. Purchasing control - in governmental operations limits are often placed on maximum dollar purchases without bids in order that the "people" and/or state administration sees that the state gets the most for its dollar.	

	REFERENCES
(1) One of the purposes of purchasing control is to "hold the line" within the budget on items which must be purchased. The acquisition of office supplies, inspection stickers, inspection equipment, motor equipment, etc., is controlled by budget and by sound purchasing practices.	
c. Audits - internal auditing provides positive control of expenditures, purchases and financial transactions. (Handling of inspection decal money, licensing fees, etc.) Generally audits are arranged for by law in a governmental operation - but additional are being made through routine review of financial actions (bookkeeping).	
D. Inspection as a control technique. (Inspection, as used in this section, refers not to the inspection of motor vehicles, but to the administrative inquiry into operations - operations in its broadest sense.)	
1. Purpose of inspection is to keep management adequately informed of all pertinent facts -	

	REFERENCES
it is related to people, programs, progress, conditions and techniques, and can provide the administrator with answers to key questions. a. It can provide analysis of operations outside the routine reporting and control techniques. It tends to provide unbiased reporting in that the reporting does not normally come from the people who are involved in the operation.	
2. Line inspection and its uses a. Line inspection is conducted by second echelon management and/or supervisors of all the work under his charge. A management control device for determining for himself how his people are performing - as such it provides a control in that subordinates are aware that they are going to have to account for their operations. (1) Line inspections in motor vehicle inspection may be conducted through direct observation of the performance of subordinates. Other techniques, of course, are to spot-	

	REFERENCES
check performances of inspection mechanics and make routine station inspections to check on accuracy of station supervisor's reports. All of this is done to see that performances are producing desired results.	
3. Staff inspections and their uses	
a. Generally staff inspections are conducted for the administrator and relate to department-wide operations. As a control technique they are:	
(1) Usually conducted as a routine and continuing function.	
(2) Fundamentally to provide the administrator with the assurance that things are going as planned. Such assurance then comes from staff which is a source outside the operations system and the assurance is not necessarily dependent upon the people who are doing the work.	

	REFERENCES
(3) Almost invariably conducted without taking corrective action which may be indicated as being needed. (This is done to avoid the dual subordination role.)	
(4) Used to check on line inspection. The exception to the rule of not taking corrective action is when circumstances indicate the organization's mission or the reputation of the organization is in danger.	
E. Summary	
1. All inspections are only a means to an end. The end product being to make certain that the quality and quantity of PMVI service is meeting the department's objectives.

SUBJECT: BUDGETING - A FUNCTION OF MANAGEMENT

HOURS: 8

OBJECTIVES: To acquaint student with the principles of budgeting; to identify types of budgets and how budgeting serves as a tool of management in accomplishing the organization's goals.

METHODS OF INSTRUCTION: This unit of instruction is designed to be presented by the lecture method. It should be supplemented with a project which requires the student to formulate a budget time schedule for the operation of a Motor Vehicle Inspection agency. Students should be encouraged to study existing budgets of PMVI agencies in order that they may get a broader picture of the types of need which occur within the field of PMVI.

INSTRUCTOR'S GUIDE

(BUDGETING - A FUNCTION OF MANAGEMENT)

I. INTRODUCTION

A. This presentation is designed to acquaint the student with the budgetary processes in a state government in which the PMVI agency is a sub-branch of a larger organization. In every state in the United States where PMVI takes place, the PMVI agency is organizationally at least three levels, and possibly four levels, below cabinet level in government. These levels are:

1. Department of Transportation, within which there is:

   a. A Division of Motor Vehicles, within which there is:

      (1) A Bureau of State Police, within which there is:

         (a) A PMVI agency.

In some states the PMVI function may be at the third level.

It is suggested that the instructor encourage students to obtain and study and discuss budgets which are published by their respective states.

Emphasis is placed, in this presentation, on the effects of the "political climate" on the success or failure of getting budget approvals. The instructor should emphasize and re-emphasize the importance of good public relations activities in PMVI in selling and reselling the PMVI program.

	REFERENCES
II. PRESENTATION	
A. Definition	
1. A budget is a comprehensive fiscal plan for a jurisdiction over an established period of time.	
a. To be comprehensive it should be all inclusive of both revenue and expenditures.	
(1) Revenues for PMVI can come from such sources as:	
(a) Sale of inspection stickers.	
(b) Direct charge for inspection of motor vehicles.	
(c) Inspection station licensing fees.	
(d) Mechanic-Inspector licensing fees.	
(e) Indirect charge based on vehicle registration fee.	
(2) Appropriations by legislature are not in a true sense revenue, but	

	REFERENCES
such appropriation is a major factor in determining monies available for expenditures.	
b. PMVI agencies are generally placed in governmental organizational structure so as to make competition for the budget dollar quite severe.	
2. The time factor will vary from one state to another although most PMVI states operate on a two-year fiscal budgeting cycle.	
a. Fiscal year may begin on a scheduled basis, usually immediately after the ordinarily scheduled end of a legislative year. A fiscal year is of twelve months duration, but most often does not start on January 1 of any given year. July 1 seems to be the usual starting time for governmental fiscal years.	
b. A calendar year is January 1 to December 31.	
c. There is nothing "sacred" about the time period when a fiscal year starts.	

	REFERENCES
There is, however, some problem with carrying projects over from one fiscal period into the next. This is usually handled by allocating or encumbering funds to meet the anticipated projects which are started in one fiscal period and which will be ended in the next. (1) Generally, operating budgets are designed to allocate expenditures during a fixed period of time and within the fiscal period, while: (2) Capital improvement budgets may require pay-off over a longer period of time and the obligation will be carried over from one fiscal period to the next. In these cases the actual amount needed for any one fiscal period is included in the operating budget for that period. (a) An example of this in PMVI might be as follows: Management decided to conduct a	

	REFERENCES
five year building program to modernize area supervisors headquarters. Construction plans are drawn with a time-table for completion of all projects within a five year span. The total cost of this program to be $2,000,000.00, of which $750,000.00 will be expended within the next fiscal year for planning and property acquisition. The operating budget would reflect the need for the $750,000.00 for the fiscal period and the Capital Improvement Budget would show the total cost and what percentage of the funds would be needed and what part of the project would be completed in the various fiscal periods up to the time of completion.	

20657

	REFERENCES
3. A budget is, in itself, not the authority for spending money but it does provide the guidelines for the legislative body to appropriate funds to meet the budgetary needs and it is from this appropriation that money will be allocated. a. In PMVI agencies the funds appropriated are often a part of funds allocated to the bureau within which the PMVI agency is located. Example: In Wisconsin, the Department of Transportation is the major governmental department in which the Division of Motor Vehicles is found, and within the Division of Motor Vehicles is located the Bureau of Policing, or the State Patrol, and Motor Vehicle Inspection (random spot inspection in Wisconsin) is under the jurisdiction of the Patrol. B. Why is a budget necessary? 1. In government there seems to be a scarcity of funds in almost every administration. Therefore, the wise PMVI administrator budgets his money, manpower and resources to	

	REFERENCES
produce the most efficient and productive operation possible. a. Limitations of funds are created by state laws in some cases. (Maximum indebtedness is stipulated.) 2. The proportion of state revenues allocated or appropriated to each branch of the government is dependent on a number of factors. a. The need (absolute) for the service being rendered. b. The available monies. c. The political expediency. (In some cases - pressure being brought to bear on the legislators.) d. The quality of the budget. (Reasonableness, demonstrated or expressed need for the service being proposed, the justification for expenditures, etc. e. The ability of the administrator of the "parent" organization, i.e., department or cabinet level administrator, to convince the legislature	

20659

	REFERENCES
of the needs.	
3. The competition for funds then requires the administrator to wisely conceive his budget, intelligently prepare the budget, and astutely present it to the legislature in order that funds become available.	
a. In PMVI the PMVI administrator has the same obligation to design his budget so as to meet the requirements set forth above. There are instances where the PMVI administrator may have to appear before the legislative committees to justify his portion of his department's total budget.	
4. Legal requirements make a budget necessary.	
a. The format used, the procedures for presenting a budget, and the time for presentation of a budget for approval may be based on law, administrative order, or both.	
b. Within the PMVI agency departmental rules will establish the format, procedure and timing of the budget.

Generally the agency budget must be submitted considerably ahead of the time that the department's budget is completed in order that the PMVI agency's section of the budget can be incorporated into the overall departmental budget. *Instructor: At this point samples of PMVI budgets may be shown along with those of the department to which PMVI is attached, to show the relationship between the PMVI budget and that of the department as a whole.	
C. The budget as a master (managerial) plan	
1. Provides for a continual evaluation of services and needs.	
a. The budget guides operations.	
b. Provides for continual evaluation of services rendered and needs - (a comparison of what is needed to do the job and what is being spent to accomplish that need. In addition, it allows a comparison of the accomplishment of the objectives of the organization against the cost of so doing).	

	REFERENCES
c. Budget assures that funds are provided for the most important services and needs first - (priorities). (1) In PMVI priority must be given to adequate inspection of motor vehicles which entails proper supervision of the inspectors and inspecting stations. Secondary priority then may be such functions as the record system, the quality of housing facilities, training, etc.	
d. A budget will highlight the cost of personnel as being one of the principal costs. (1) Management, therefore, has the obligation to get maximum efficiency from that personnel.	
e. The budget helps to sell the PMVI program to the appropriating authority. It should also strengthen the department administrators opinion and evaluation of the PMVI program. (It is assumed that the PMVI agency is a section within a larger organization.)	

20662

	REFERENCES
D. The budget acts as a fiscal control 1. Provides PMVI administrator and others (auditors and department administrator) with fiscal checks and balances. a. Money spent for specific items, services or needs must have been appropriated and expenditures must be kept within the amounts allocated. 2. Budget is a tool for decision-making. a. When expenditures are exceeding monies allocated, management must make adjustments. (1) To slow down expenditures. (2) To adjust to meet increased spending if priorities warrant the adjustments. 3. The budget provides and calls for a review of actions before they are taken, i.e., if PMVI agency administrator plans a function he must, as a part of his planning, determine if monies are av ailable and budgeted for. If the action planned is not within the planned budget then adjustments and location of funds is essential.	

20663

	REFERENCES
4. The fiscal control that is found in PMVI budgets and, in fact, in most all budgets is often not primarily exercised by the administrator. The departmental auditor, state auditor, or budget control officer (title is not significant for such a person may be at staff level) maintains the records. He informs the administrator of expenditures and balances. If the process of informing the administrator is slow or the procedures for authorizing expenditures before actual spending are poor the administrator may find accounts overspent before he is aware of it. a. To circumvent this problem in PMVI agencies it is recommended that record-keeping procedures be adopted so that the budget source of funds for expenditures is indicated before expenditure is authorized.	
E. The Budget Process 1. The Budget directive. a. A budget directive is a device in which the chief administrator sets forth the anticipated performance of his organization during the period covered by the	

20664

	REFERENCES
budget. He states his justification for making the expenditures for which money is being requested and in general"sets the stage" for consideration of his budget by the legislature. (1) The administrator, before preparing his budget directive, will have called for needs for budget items from his organization. It is well at this point for the student to again recognize the position of the PMVI agency in the organizational structure of government. (a) To start with, by law, the governor will call for a submission of a budget. This call is transmitted to the department administrator (generally a cabinet level person). The departmental administrator then charges each of his divisions to prepare divisional budgets. The division directors will then advise bureau chiefs to prepare	

	REFERENCES
their budget requests. The bureau chiefs will call upon section or agency heads to set forth their needs for the coming budget year or years. The agency head may then ask his subordinates to estimate their budgetary needs and these persons often will ask the field supervisors and operational employees to outline needs for the next budget period. It is evident, then, that the call for the submission of a budget may, in some manner, involve nearly everyone in the organization. PMVI agencies are no exception to this concept. (2) The executive budget directive (call for budget submission) (a) Should set forth a general budget policy.	

20666

	REFERENCES
(b) May stipulate that there must be justification for all requests. (c) Demand necessary supporting information and the type of data needed. (d) May ask for specifics such as: (1) Personnel needs (2) Capital outlays (3) Exact figures on equipment needs. b. Require detailed information on procedures (justification on basis of 'best-possible-way'). This makes PMVI personnel cost conscious. 2. The budget calendar is a prerequisite to good budgeting. a. The governor has a specific date for submitting budget to legislature..usually far enough in advance to allow legislative committees time to probe and decide, but not so long in advance of time of	

	REFERENCES
actual need as to allow legislators an opportunity to kill the budget entirely. (This can happen and the Governor would have to call emergency sessions of administrators to re-submit). Timing to the Governor and legislature is important, therefore. Budgets are often one of the last items on a legislative agenda before adjournment. b. After the Governor's call the departmental administrator sets up the time for the submission of the division budgets. The division establishes the bureau's budget and the bureau sets a time for submission of budget items from sub-bureaus or agencies within the PMVI agency. The PMVI agency may call for submission of items from the "field". The whole process, therefore, must be well-timed with each of the levels allowing adequate time for them to assemble their budget facts and to	

	REFERENCES
submit them, through channels, to their immediate superiors. *Instructor: A portrayal of this time span can be either drawn on the board or shown graphically with overhead projector or slides, or have students estimate a budget calendar as a project. It is estimated that there may be as much as eight months between origination of first line budget considerations until the budget is finally approved by the legislative body.	
3. Budgetary phases a. Preparation phase (1) The flow-up and feed-back continuum. Everyone in the organization should have an opportunity to suggest budgetary needs and at the same time management should request this type information. As a matter of procedure in PMVI operations management will aid this flow if they can keep subordinates informed on why certain budgetary proposals are not incor-	

	REFERENCES
porated into the budget. An example of this flow-up and feed-back continuum is shown in the following situation: A station supervisor, in a routine visit to a neighboring state, observes a new type of calibration device which he believes is more efficient than those being used by his state. At budget time the station supervisor proposes the state acquire x-number of these instruments. Management is informed of this item. Management has already considered this item and has concluded that they will replace the existing calibration devices with another type when the present ones are due for replacement. This decision is then returned down to the originator of the item.	
(2) Definition of goals - in the budgetary process it is essential that management at all levels define, in terms of budgetary items, what their

	REFERENCES
goals are -- what they expect to accomplish, what new or different operations they plan.	
(3) Analysis of needs - throughout the PMVI agency there should be a constant evaluation of what is needed to perform the agency's function. In addition to determining what routine needs are, management should through planning be considering future needs.	
(4) Development of plans - as plans are made for future operations, budgetary needs are indicated and as budget "time" comes due these needs are included in the budget .	
(5) Estimation of cost - in estimating cost in PMVI as in any other organization management has to consider future cost as opposed to current cost. Labor, as an example, has a constant rise in cost. Most materials used in PMVI, i.e., forms,	

20671

	REFERENCES
stickers, equipment, motor vehicles, etc., cost more each year. Management may consider trends in rising cost over the last few years and using these trends as guidelines, estimate future cost.	
(6) Compilation of the budgetary document.	
(a) After the person preparing the budget has assembled the necessary information, the actual preparation of the budgetary document requires that it meets the legal requirements, if applicable, and the requirements as established by the administration and/or the legislative body.	
(b) The format of the budgetary document will be dictated normally by at least these considerations:	
(1) Requirements of the administration.	

	REFERENCES
(2) The legislative committee use of the document. In most cases the format will have been established by prior experience and acceptance. (7) Submission and adoption of the budget. (At this point it is assumed that the compilation of the budgetary document of the "parent" department has gone through the process of bureau, division and agency compilations and that it has been accepted by the administrator of the department for submission to the Governor and/or the legislature and their sub-committees.) (8) The administrator prepares a budget message which accompanies the submission of the budget to the legislature. The context of this message will include a statement of proposed programs, the needs for the programs and what it will cost	

	REFERENCES
to perform them, and the cost of service to be rendered. (9) The budget is then assigned to a committee within the legislature for review and consideration. 4. The final approval of or acceptance of a budget by the legislature is affected by relationships which, while unofficial, have a bearing on the willingness of the responsible people to accept the budget request. These in PMVI are: the working relationship between the PMVI agency head and his immediate superiors. The better the communications, the better the acceptance of the proposed budget may be. The wise department administrator recognizes the need for cultivating key people in the legislature. In fact, in some cases the administrator becomes his own best, or worst, lobbyist depending on his understanding of the political climate.	

	REFERENCES
The administrator also must take cognizance of pressure groups who can effect his budget request. In PMVI it is reasonably certain that support for PMVI will come from garages and agencies who can expect financial gain from the inspection operation. Opposition to inspection may not be as well organized, but a few irate citizens writing to key legislative members can create problems for the PMVI agency in getting funds allocated. In PMVI the administrator and the PMVI agency head must constantly be aware of the need for good public relations in order to combat negative pressures on the program. This good PR work will "pay-off" at budget time. 5. The administrator, in making his presentation before the legislative committees, should: a. Place emphasis on the objectives of his organization.In PMVI this is the reduction of death and injuries in accidents as the result of motor vehicle traffic accidents.	

	REFERENCES
b. Be able to support factually any request he makes in the budget message or body of the budget.	
c. Have considered alternatives to his proposals and be prepared to defend the proposals. He must also be willing to accept alternatives if he cannot get acceptance of his original proposals.	
d. He must relate cost to the activity proposed.	
e. Prepare necessary exhibits, visual aids, charts, etc., to present his factual information.	
f. Be prepared to acknowledge when he is estimating needs or cost for lack of any experience which can give him a "handle" on actual costs.	
g. Prepare and handout a legislator's information kit. He must avoid, in this area, however, the idea that the kit was an expensive undertaking.	

20676

	REFERENCES
6. In summary - the success of presenting a budget and getting acceptance of it is dependent on:	
a. Good staff work in assembling information.	
b. Good planning for future operations.	
c. Successful performance in the past.	
d. Determining needs	
e. Building proper rappaport with legislature, administrators, pressure groups and interested citizens.	
F. Execution of the budget (use of)	
1. Once the budget is approved and the legislature allocates the funds, the administrator:	
a. Makes an analysis of the accepted budget to determine exactly what he has to work with in terms of dollars, manpower and other resources.	
b. Makes plans to perform based on availability of resources and allocates these resources throughout the organization.	
c. May have to re-evaluate operations on	

	REFERENCES
the basis of changes made by the legislature. This requires further staff work, planning and setting priorities for performance.	
2. The expenditure process from budgeted items will follow a pattern similar to the following:	
a. Request for budget item expenditure is made. Example: Field supervisor needs a new car.	
b. Staff personnel reviews request, determines need and approves purchase.	
c. Audit at this point may be made to determine if money is available and if contract meets legal requirements. If so:	
d. Money is encumbered, and:	
e. Purchase order is made up, following which the car is:	
f. Delivered and acceptance is noted. This is called:	

20678

	REFERENCES
g. Certification of purchase and delivery, which, when received in finance office is the order for:	
h. Payment for the car.	
3. In the accounting process of PMVI organizations there should be a "running inventory" of how much has been expended in each account and what the balances are.	
a. When management is informed that expenditures are running ahead of budget expectations, they should review the operations to determine corrective measures.	
G. Types of Budgets	Ref. #1 - pp. 11-14
1. Introduction	
a. The choice of the type of budget to be used by an administrator in presenting his budget to the legislature will vary from one jurisdiction to another. There are three principal types of budgets in use today.	
(1) Line Item Budget, sometimes referred to as an Object Budget.	

	REFERENCES
(2) Program Budget (3) Performance Budget The differences between the three budgets may be indicated by the following simple examples: (1) A Line Item Budget itemizes the individual cost for personnel, equipment, material and services for the PMVI agency to perform its overall task. No special attention is given as to what it costs to perform the individual functions within the agency. (2) The program budget indicates the cost of conducting various phases of the PMVI agency without showing the cost of doing the individual unit performance of that task. An example is: A program budget will stipulate x-number of dollars for licensing of inspector-mechanics, but this will be no indication of the cost to license an individual

	REFERENCES
mechanic. On this basis the administrator has budgeted x-dollars for licensing and projected what his total cost will be.	
(3) In performance budgeting the administrator establishes his programs and then computes the cost of performing each individual function. On this basis he submits a budget request which is based on units of activity. An example of this: The PMVI agency will license y-number of inspection mechanics in the coming budget year. The cost for licensing one mechanic inspector is x-dollars. Therefore, xy dollars are needed to license mechanic-inspectors for the coming budget period.	

In summary - a simplification of the above - Line Item Budgets itemize individual object cost without specific regard to the unit programs; Program Budgets deal with cost of programs with minimal reference to item cost or performance cost; Performance Budgets compute cost on numbers of units of activity

	REFERENCES
to be performed at a cost per unit.	
2. The Line Item Budget	
a. The Line Item Budget is the traditional approach to budgeting.In this form of budget submission the administrator itemizes the cost of performing the services of the organization in terms of quantities, i.e., people, supplies and contractural services. He then computes the cost to provide these items. (A sample type budget accompanies this unit of instruction.)	Ref. #3 - All
b. The advantage of the Line Item Budget is its simplicity. The department using this form of budget can operate it with a minimum of budgetary expertise.	
(1) The Line Item system can be operated with a non-complex type of accounting. The fact that it itemizes expenditures makes it fairly simple to keep track of cost vs expenditure.	

	REFERENCES
(2) The Line Item Budget allows for easy statistical comparisons from one year to the next.	
(3) Legislatures like the Line Item Budget approach for it is easy to understand and simple to evaluate and pare.	
c. The disadvantage of the Line Item Budget approach:	
(1) The preparation of the budget becomes so involved in computing unit cost that sight is lost of the full objectives of the organization. There is more attention to dollars, units of personnel, equipment and supplies than to the unit or organizational objectives. Less attention is paid to the amount of work the dollars are accomplishing.	
(2) The Line Item Budget creates a problem in evaluating the cost of programs within the PMVI function. Example: In a department using the Line Item Budget the administrator	

20683

	REFERENCES
may know that personnel is costing x-number of dollars but without making some special studies he cannot determine what it costs to conduct an investigation of a station for licensing purposes. (In Performance Budgeting he would know this cost.)	
(3) In Line Item Budgeting the administrator loses some flexibility in adjusting to meet contingencies,for he is held accountable to a fixed cost for each specific item of expense. Management, therefore, loses some element of decision-making to the "sharp pencil" of the accountant.	
d. The Line Item Budget can be used in conjunction with adequate accounting procedures to determine program cost or performance cost. This is often what is done in the PMVI service. Example: The agency will extract from the budgetary cost the exact cost of personnel, supplies, equipment, material, space,	

	REFERENCES
etc., to conduct training. This would involve computing the cost for only the personnel, time, materials, etc., when such costs were directly related to the training. The PMVI agency can cover program costs by coding expenditures on the basis of type of service performed in order that analysis can be made of the program cost at some later date. With this type of accounting the administrator can be kept informed of program and/or performance costs. 3. The Program Budget a. The Program Budget is designed to show the cost of programs being carried on within the organization. Examples in PMVI are: (1) Licensing of mechanic-inspectors. (2) Licensing of inspection stations. (3) Training of mechanic-inspectors. (4) Supervision of stations and inspectors.	

	REFERENCES
(5) Training of departmental personnel.	
(6) Management of PMVI function.	
(7) Calibration of equipment.	
(8) Research	
(9) Etc.	
b. Advantages of the Program Budget	
(1) This budget allows the administrator to have a better understanding of the relative cost of each of the programs carried on within the organization.	
(2) Trends in program costs can be better followed.	
(3) The administrator is not held to the fine degree of accounting as is found in Line Item Budgeting and, therefore, there is more flexibility in adjusting expenditures within the program.	
c. Disadvantages of the Program Budget	
(1) In Program Budgeting cost distributions within sub units of the	

20680

	REFERENCES
organization tend to be lost (not accounted for). Example in PMVI: The licensing of mechanic-inspectors would involve the training unit, the field supervision unit, accounting unit and supplies, while the cost of licensing all inspector-mechanics would be known, the ratio of cost per sub-unit would not be known. Program Budgeting doesn't allow for exact costing of management or supervisory overhead.	
(2) In presenting Program Budgets to the legislature, some factors which affect cost may not be clearly identified. (The budget directive and justification for cost estimates may cover this, but when this is done the budget process becomes partially a Line Item Budget.)	
(3) Another disadvantage of the Program Budget is the need for greater expertise in staff work in computing the cost of programs.	

20687

	REFERENCES
4. The Performance Budget a. A Performance Budget is designed to show the cost of each unit of activity within a PMVI program. As an example: The Performance Budget for PMVI in the program of licensing mechanic-inspectors would show the individual cost of licensing one mechanic-inspector and then project the total cost for performing that service. In computing these costs the administrator considers: (1) Departmental manhours per each license for: (a) Background investigation. (b) Departmental training for applicant before licensing. (c) On-the-job testing of applicant, etc. (2) Cost of certificate. (3) Accounting cost - supplies, etc. b. Advantages of the Performance Budget (1) The Performance Budget more clearly permits management to determine the	

	REFERENCES
relationship between resource input and the service output. As an example: If it cost $139.00 to conduct the investigation and to license one inspector-mechanic, and the license fee collected is $5.00, there is no doubt that management will begin to look for more efficient ways to accomplish the licensing. (a) Another advantage is that the legislative committee can see exactly what costs are for individual services rendered. (b) This type of budgeting places greater responsibility on program managers (management) to render their service within the cost estimate. c. Disadvantages (1) In PMVI the Performance Budget concept requires a more detailed accounting system and qualified budget personnel.

ABSTRACT - Developed by the Education Department of the National Restaurant Association, this guide is for instructor use in developing a training program in quantity food preparation. Topics are: (1) Basic Principles of Quantity Food Preparation, (2) Science Related to Food Preparation, (3) Mathematics Related to Food Preparation, (4) English Related to Food Preparation, and (5) Safety Instruction. The content suggested for each subject area has been outlined under the three phases of instruction which include essential learnings, scope of instruction (suggested content), and technical and related information. The curriculum outline may be adapted to a 2- or 3-year course as part of a high school program or a specialized trade program. Job descriptions, teaching materials, and supplementary teaching materials are appended. (SB)

	REFERENCES
3. Performance Budgeting requires greater expertise in preparation and in use than do the other two types of budgets. It provides management with a closer evaluation of the exact cost and benefit from each individual action within the programs of the organization. A disadvantage of Performance Budgeting in PMVI is that there are functions in the operation which cannot be "broken down" into individual performance cost; public relations operation as an example.	
4. A budget is a tool of management and should be used as a guideline, not as an objective in itself, i.e., run an operation to stay within the budget as opposed to meeting the operational objective.

SUBJECT: MANAGEMENT PROBLEM-SOLVING SEMINAR

HOURS: 4

OBJECTIVE: To provide the student with current information in selected areas of motor vehicle inspection program management; to provide the student with a means of discussing supervisory and management problems with recognized experts in the motor vehicle inspection field.

METHODS OF INSTRUCTION: Instruction in this unit should be based on questions which the students would like to have discussed by a panel of experts.

Each student should be requested to submit a series of questions. The questions should be collated and submitted to panel members at least a week in advance of the discussion.

Panel members should consist of people who are recognized authorities in one or more phases of vehicle inspection. The course coordinator should serve as a panel member.

SELECTED READINGS ON MOTOR VEHICLE INSPECTION

2045

AAA Foundation for Traffic Safety. A study of motor vehicle inspection: final report, conducted by...and Arizona State University Division of Industrial Design & Technology. Washington, Apr.1967. 70p.+ charts, form, tables, bibl.

Contents: Introduction.- Summary.- History of motor vehicle inspection.- State-of-the-art of motor vehicle inspection.- Probable future trends in motor vehicle inspection.- Effectiveness of motor vehicle inspection in preventing accidents.

A separate summary issued for this report also updates information on individual state programs to July 1, 1967.

American Association of Motor Vehicle Administrators. Motor vehicle inspection reference guide, by...and Auto Industries Highway Safety Committee. Washington, 1964. 2pts. charts, tables.

pt.1. Motor vehicle inspection in perspective.- pt.2. The answerfinder.

"The purpose...is to provide in a readily applicable format (a) basic information about periodic motor vehicle inspection, (b) pointers on organizing and working for MVI, (c) pointers on administering an inspection program in the first 24 months of operation, and (d) pointers on upgrading an established MVI program." - Outline.

American Association of Motor Vehicle Administrators. Vehicle inspection reciprocity agreement. [Washington, 1967?] 2p.

Text of agreement granting reciprocity on vehicle inspection.

American Petroleum Institute. Periodic motor vehicle inspection programs, pt.1. Procedure guidelines. New York, May 1967. 21p. Publ.1571. $.35.

This report makes recommendations to help state petroleum organizations and the oil industry work effectively with state motor vehicle inspection agencies. The report presents the consensus of oil companies and dealers who have had experience with existing programs. It seeks to answer these questions: "What items should be included in a good inspection? What requirements should be met to pass? What equipment the inspector should have?"

American Petroleum Institute. Periodic motor vehicle inspection programs, pt.2. Organization guidelines. New York, Aug.1968. 40p. bibl. Publ.1572. $.50.

"These Organization Guidelines pinpoint the essential components needed for sound administration, supervision, and enforcement of a state's periodic motor vehicle inspection program."

Arizona. Motor Vehicle Division. Motor vehicle safety inspection in perspective. [Phoenix, 1966?] 73p. tables.

The program and its repeal in Arizona including general discussion on essential requirements for PMVI systems and a detailed cost analysis of state programs. A recommended plan for periodic vehicle inspection in Arizona is presented.

Automobile Club of Missouri. Used car safety standards (vehicle safety status): final report, by F.B. Oldham, prepared for U.S. National Highway Safety Bureau, Contract no.FH-11-6915. St.Louis, July 31, 1969. 2v.in 4. charts, tables. Distributed by CFSTI (PB 187658-61).

Reports of defects found during examination of 8000 cars in the Auto Club's inspection center. Total defects and potentially dangerous defects as well as data on car use, servicing, storage and mileage are tabulated by make, model and year. Discussion includes information on most common defects, required inspection equipment and procedure and research needed to establish relationship of vehicle condition to accidents. The author concludes that "brakes, tires and steering geometry should be inspected twice annually, while the remainder of those items normally included in State inspections should be examined only once a year".

Automobile Club of Southern California. Compulsory periodic motor vehicle inspection. [Los Angeles] Sep.1966. 24p.+

Review of types of systems, arguments for and against inspection, research on efficacy. Recommendations that the Club oppose compulsory periodic motor vehicle inspection and support the inspection program as presently conducted by the California Highway Patrol.

Automobile Manufacturers Association. Inspection handbook for passenger cars and station wagons, trucks and buses, motorcycles, school buses, foreign vehicles through 1969 models with manufacturers' recommendations, prepared by...in cooperation with the American Association of Motor Vehicle Administrators. [Detroit] Jan.1970. var.paged. diagrs., tables.

Contents: Registration.- Wheels and tires.- Steering alignment and suspension.- Brakes.- Lighting and electrical.- Glazing.- Body and sheet metal.- Exhaust and fuel systems.- Vehicle emission control systems.

"This handbook is...a guide for both the individual inspector and for the person responsible for planning and implementing a meaningful program based on sound engineering principles." - Introduction.

Automobile Manufacturers Association. Subject summaries of...state legislation. Detroit. annual.
Section 8. Vehicle inspection.

Automotive Safety Foundation. A fact-gathering guide to assist states in developing a highway safety program. Washington, 1968. var. paged. bibl.
Periodic motor vehicle inspection, p.8.1-8.14.
Presents study outline covering legal authority, rules and regulations, selection and training of inspection personnel, statistical data for state inspection programs.

Automotive Safety Foundation. Highway safety program management [v.2] Transcripts of regional safety program management seminars conducted for the U.S. National Highway Safety Bureau under Contract FH-11-6537. Washington, Aug.1968. 125p. illus., charts, diagrs., maps, tables, bibl.
Motor vehicle inspection, p.47-53.
Discusses research which tends to correlate vehicle inspection with accident reduction and describes random and periodic inspection procedures among the states. Suggestions are given on basic elements for a state inspection statute and administrative rules and regulations. Significant program problems presently encountered are outlined.

Automotive Safety Foundation. Maryland's highway safety needs in periodic motor vehicle inspection, by Anthony Antony [for Maryland State Roads Commission] Washington, 1969. 92p.
Maryland's past, present, and future program of motor vehicle inspection as related to NHSB requirements.

Automotive Service Industry Association. The reasons for periodic motor vehicle inspection. Rev. Chicago, Dec.1964. 85p. tables.
Partial contents: Comparison of motor vehicle fatality rates, with and without PMVI.- Registration and percent rejections in PMVI states.- Comparison of PMVI state by state.- Typical defect analysis in PMVI states.- PMVI system in detail (Massachusetts).-Rules & regulations concerning PMVI - Massachusetts.- Inspection station requirements.- Sample cost analysis of a state PMVI.- Uniform Vehicle Code on PMVI.- Sample of state PMVI bill.

Boodman, David M. Safety and systems analysis, with applications to traffic safety. Law and Contemporary Problems, Summer 1968, p.488-511.

"The systems analysis approach to the traffic safety problem requires careful consideration of a variety of programs intended to reduce the hazards of the system as they exist in the vehicle, the driver, the environment, or the legal and regulatory features of the system." - Summary.

Booz-Allen and Hamilton. Safety specialist manpower, prepared for U.S. National Highway Safety Bureau, Contract no.FH-11-6496. Washington, Oct.14, 1968. 4v. forms, tables. Distributed by CFSTI (PB 182068-71).

Brenner, Robert. Some trends and views on new car and used car safety performance standards [presented at] Society of Automotive Engineers Detroit section, April 15, 1968. New York, Soc.of Auto.Eng. 5p.

"The safety of motor vehicles is discussed in relation to: the development and application of new and used car safety standards; the improvement and standardization of motor vehicle inspection programs; and comprehensive engineering and economic studies to guide the application and development of standards themselves." - Abstract.

Burnstine, Murray. Some defective vehicle conditions in traffic death cases. Aspects Tech.de la Sec.Routiere, Mar.1965, p.3.1-3.30. illus.

Reprinted from Research on fatal highway collisions (Harvard Medical School).

Study indicates the ineffectiveness of the Massachusetts vehicle inspection program. Thirty-two vehicles involved in collisions were analyzed for defects. The observations reported are not exclusively collision-causal defects; however, ascribing cause to the driver or the road without fully analyzing the vehicle may result in misinterpretations of cause.

Buxbaum, Robert C. Relationship of motor vehicle inspection to accident mortality, by...and Theodore Colton. J.of the Am.Med.Assn., July 4, 1966, p.31-36. charts, tables, bibl.

"The role of mechanical failure in automobile accidents is examined by comparing motor vehicle mortality among men, age 45 to 54, in states which do and do not require motor vehicle inspection. Inspection is associated with lower mortality, and this association prevails under varying economic, geographic, and demographic conditions. Furthermore, comparison of white to nonwhite death rates reveals that nonwhites are at consistently greater risk." - Abstract.

Criticism of variables used in this study appears in report: Safety Research Manpower (North Carolina University Highway Safety

Research Center, June 1968) developed for traffic safety research personnel training.

California. Legislature. Assembly. Committee on Transportation and Commerce. Motor vehicle inspection; report of the..., January 7, 1963. [Sacramento] 71p. charts, map, tables, bibl.

Background report on the need for vehicle inspection in California describing advantages and disadvantages of state and private systems, past and present programs in other jurisdictions and a review of inspection legislation in California. From its study and hearings the committee recommended that investment in increased traffic law enforcement and current inspection procedures (random, brake and light) would be more effective than investment in PMVI.

California Traffic Safety Foundation. Opinion poll of California licensed drivers, by Earl F. Campbell, J. Arthur Rude and Royal A. Neilson; survey conducted...in cooperation with California Department of Motor Vehicles. San Francisco, Jan.1965. 180p. tables, map.

Tabulation of replies to 34 questions relating to traffic laws and driving. Question 12: Do you believe there should be a law requiring periodic inspection of all motor vehicles for safe mechanical condition? Answers were substantially affirmative.

Carmichael, Glenn V. Periodic motor vehicle inspection. Washington, AAMVA [1964?] var.paged.

This report concludes that PMVI programs have been successfully conducted on a state-wide basis for more than thirty years. Selection of a system should be made only after a full survey and study of the special needs and circumstances of the particular state. An important element in a successful MVI program is a thorough public information effort.

Chayet, Neil L. Motor vehicle inspection. (in Curran, William J., ed. Trauma and the automobile. Cincinnati, W.H. Anderson, 1966) p.66-88. illus., tables.

Statistics, though not conclusive, appear to indicate that compulsory MVI has reduced accidents. The author recommends state-operated systems as opposed to private inspection.

Cline, E.L. Development of techniques and equipment to improve reliability of automotive diagnosis [presented at] Society of Automotive Engineers midyear meeting, Chicago, May 15-19, 1967. New York, Soc.of Auto.Eng. 15p. illus., charts, diagrs. 670517. $1.

"Findings obtained through mass diagnosis provide a practical insight, useful in the development of: multiple personnel work procedures, efficient facility layout, testing techniques that answer field service problems, equipment and personnel education that implement these techniques, and solutions to novel architectural problems inherent with indoor vehicle operation." - Abstract.

Colton, Theodore. Motor vehicle inspection and motor vehicle accident mortality, by...and Robert C. Buxbaum. Am.J.of Pub.Health, June 1968, p.1090-1099. charts, map, tables, bibl.

An extension of the authors' earlier study (published in the Journal of the American Medical Association July 4, 1966) to consider accident deaths for all ages, both sexes and whites and non-whites by inspection and non-inspection states with covariance adjustment for other accidents, population density and per capita income. "...results support the hypothesis of an effect of inspection on motor accident mortality, but its magnitude is considerably smaller than that suggested by our previous report."

Cornell Aeronautical Laboratory. A program plan for developing safe handling standards for motor vehicles, by Fred Dell'Amico, prepared for U.S. National Highway Safety Bureau, Contract no.FH-11-6529. Buffalo, Sep.1967. 175p. illus., charts, diagr., tables, bibl. CAL Rpt.no.VJ-2494-V-1. Distributed by CFSTI (PB 177617).

"State-of-the-art reviews have been conducted in motor vehicle handling qualities, handling qualities evaluation procedures, driver skill demands, braking system technology, and the relationship between vehicle handling and safety... There is no general body of objective evaluation technique." - Summary.

Coucke, Edouard. Vehicle fitness, pt.1-2. Aspects Tech.de la Sec. Routiere, Mar.1965, p.4.1-4.39; June 1965, p.3.1-3.29. charts, tables, bibl.

Motor vehicle inspection in Belgium and abroad. Gives a classification of and statistics on defects of vehicles, based on a study done in Belgium. Includes discussion of "type approval", or fitness of a definite model of vehicle in relation to design and construction, as applied in Belgium.

Coverdale & Colpitts. Report on an evaluation of motor vehicle inspection. New York, Apr.14, 1967. 48p. charts, tables.

Existing MVI programs are evaluated, based on "interviews with manufacturers of inspection equipment, the supervisors of inspection programs, observations of inspections being made, and [Coverdale & Col-

pitts] reading of the rules under which the programs are conducted." Transmittal letter.

Coverdale & Colpitts. Report on recommendations regarding motor vehicle inspection. New York, May 4, 1967. 18p. tables.
Follow-up to the authors' Report on an evaluation of motor vehicle inspection. The study recommends inspection by licensed agencies (garages or diagnostic centers) equipped to carry out necessary maintenance, inspection of vehicles twice yearly but with the program scheduled throughout the year rather than at specific time periods, with supervision of the program under the director of the state police or his equivalent.

Coverdale & Colpitts. [Recommendations for a preferred statewide periodical motor vehicle inspection program, submitted to Office of Traffic Operations, U.S. Bureau of Public Roads] New York, July 5, 1967. 7p.+ table.
Recommendations on provisions of inspection laws, program administration and enforcement.

Eagles, Joseph E. Legislator outlines steps taken to win vehicle inspection bill for North Carolina. Traf.Dig.and Rev., Mar.1966, p.16-18.
Political considerations which influenced passage of new inspection legislation in North Carolina.

Frey, Thomas J. Private vehicle inspection operates as an arm of the municipal garage in Cincinnati, Ohio. Am.City, Apr.1969, p.112-113. illus.
Description of inspection lane operations, facilities, fees and costs.

Fuchs, Victor R. Motor accident mortality and compulsory inspection of vehicles, by...and Irving Leveson. J.of the Am.Med.Assn., Aug. 28, 1967, p.657-661. tables.
A follow-up of the Burbaum-Colton study published in Journal of the American Medical Association (July 4, 1966). In this report, age-adjusted death rates by states are regressed on inspection and other variables such as population density, age of drivers and alcohol consumption. The authors conclude inspection can reduce highway deaths by 5-10 percent but cost-benefit analysis does not indicate effectiveness of inspection over other traffic safety measures.

George Washington University. State-Local Finances Project. Planning-programming-budgeting for city, state, county objectives, PPB note 10. Program objectives, effectiveness criteria and program structure; an illustration for highway safety. Washington, July 1968. 17p. tables.

Note developed by Jack Cotton as a special project for the State College of Arkansas and the Rockefeller Brothers Fund.

Suggested elements of state highway safety program include inspection as a minimum standard in maintenance/improvement of vehicle safety characteristics.

George Washington University. State-Local Finances Project. Planning-programming-budgeting for city, state, county objectives, PPB note 11. A first step to analysis: the issue paper. Washington, July 1968. 22p. tables.

A useful guide to PPBS.

Houck, L.H. Mo. inspection law likely to stir woes, pt.1-4. Auto. News, Nov.18, 1968, p.40; Dec.9, 1968, p.14; Jan.20, 1969, p.35; Mar.10, 1969, p.23.

pt.2. Inspection started under new Missouri law.- pt.3. Car inspections stir tempest in Missouri.- pt.4. Mo. revising inspection law.

Criticisms of program administration and lack of profit for dealers performing inspections. Response of State Highway Patrol officials. Repeal introduced, but defeated; House of Representatives committee working to improve present law.

Huddleston, Bert. Oklahoma's compulsory vehicle inspection program. Law and Order, May 1969, p.40-41+

Reviews complaints against the inspection law as too stringent and requiring too many repairs. Suggested modifications of the law were: (1) deletion of all areas wherein the judgment of the individual inspector was involved; (2) modification of standards for shock absorbers, brakes, wheels, exhaust systems, lights, horns, windshields and tires; (3) extending time allowed for repairs.

Insurance Institute for Highway Safety. Management manual for motor vehicle inspection. Washington, Jan.1, 1968. var.paged. charts, diagrs., forms, tables.

Contents: Purpose, objective, and need for periodic inspection programs.- Development of a motor vehicle inspection program.- MVI resource requirements.- Operating policies and procedures.- Report requirements.- Program development management plan.

Keene, Jenness M. Rx 'clinic' goes to the fleet [new concept in diagnostic centers for Pacific Telephone and Telegraph] Fleet Owner, July 1969, p.72-75. illus.
Mobile diagnostic unit used in San Francisco Bay area.

The Sunoco Car Care diagnostic center.

Little (Arthur D.) The state of the art of traffic safety; a critical review and analysis of the technical information on factors affecting traffic safety, prepared for the Automobile Manufacturers Association. [Cambridge, Mass.] 1966. 2pts.in 1 (624p.) charts, tables, bibl.
Compulsory vehicle inspection, p.274-285.
Contents: Introduction.- Information reviewed.- Views of official bodies.- Legislative attitudes.- Administration of inspection.- Findings of inspections.- Evaluation of compulsory inspection.- Vehicle deterioration as a factor in accident causation.- Summary and evaluation.

Little, Joseph W. Highway safety programs and the public trust. Traf.Q., Oct.1968, p.469-477.
"...PMVI can serve the public good but...its implementation should be accompanied by realistic scientific research to establish the value of PMVI; the evaluation of alternate programs such as check-lanes; and continual program review to insure sympathetic response to the demands of the public, quality inspections, and honesty."

Little, J.W. Politics and vehicle inspection in the United States. Aspects Tech.de la Sec.Routiere, no.35, 1968, p.4.1-4.17. tables.
Acceptance by the states of federal standards on motor vehicle inspection. The authors surveyed state PMVI authorities on their programs for the influence of the Highway Safety Act, public reaction, effect on traffic safety and evaluation. Non-PMVI states were queried on the outlook for legislation.
The study was also issued as University of Michigan Highway Safety Research Institute report PuF-8 (September 1968).

Lowrey, Francis P. Vehicle condition and periodic safety inspections. (in Association for the Aid of Crippled Children. Passenger car design and highway safety. New York, 1962) p.109-122. Includes discussion.
Brief review of vehicle condition as a factor in accidents, inspection programs and trend toward recognition of inspection as a factor in accident prevention.

Michigan State University. Highway Traffic Safety Center. Public opinion in Michigan on traffic accident prevention: preliminary report. [East Lansing] Jan.1966. 39p.+ tables.

"This study was conducted to obtain precise estimates of how serious Michigan residents judge the state's traffic and accident problem and what they think should be done about the situation."

Section F: Car safety and vehicle inspection, p.30-33.

Michigan State University. Highway Traffic Safety Center. Study report and plan for periodic vehicle inspection in Michigan. [East Lansing] Dec.1964. 59p. maps, tables.

Partial contents: Essential features of a good periodic motor vehicle inspection program.- Financing of periodic motor vehicle inspection.- Recommended plan for periodic vehicle inspection in Michigan.

Michigan. University. Highway Safety Research Institute. The influence of periodic motor vehicle inspection on mechanical condition, by Robert W. McCutcheon and Harold W. Sherman. [Ann Arbor] July 1968. 68p. illus., charts, forms, tables, bibl. Rpt.PhF-1. Distributed by CFSTI.

Observations at inspection sites in four cities "indicate that vehicle populations subject to periodical inspection are in substantially better mechanical condition than populations not subject to inspection..., that the mechanical condition of a vehicle population is substantially improved as the frequency of inspections increases, and that the number of defects per rejected vehicle decreases as the frequency of inspection increases." - Abstract.

A revised version of this study was published in Journal of Safety Research, December 1969.

Michigan. University. Highway Safety Research Institute. Motor vehicle inspection administration: a critical review, by Joseph W. Little. Ann Arbor, June 1967. 51p. charts, form. Distributed by CFSTI (PB 174919).

Surveys administrators of state inspection programs. Problem areas of internal administration and public relations are discussed, with recommendations for administrative organization, inspection organization and procedures, and enforcement.

MICROCOPY RESOLUTION TEST CHART
NATIONAL BUREAU OF STANDARDS-1963-A

New Jersey. Legislature. General Assembly. Subcommittee on Transportation. Compulsory periodic motor vehicle inspection in New Jersey. [Trenton] Jan.1964. 71p. charts, tables, bibl.

Study of New Jersey state-operated PMVI program with recommendations to continue the program but institute modifications to exempt vehicles less than two years old, and shorten the re-inspection period for defective vehicles.

Appendices: motor vehicle inspection in the U.S., scope and costs of the New Jersey program, motor vehicle inspection and accident research.

Newman, John. Vehicle inspection a success in New Jersey. Hwy.User, Dec.1965, p.21-23.

New Jersey's state owned and operated system.

North Carolina. University. Highway Safety Research Center. Periodic motor vehicle inspection in North Carolina: a descriptive study, by Donald W. Reinfurt and Edward A. Pascarella. Chapel Hill, Nov.1969. 47p. charts, tables.

Data on failure rates and repair charges for inspected vehicles in North Carolina. Their relationship to vehicle age, mileage and presumed driving environment is charted.

O'Day, James. The breakdown of periodic motor vehicle inspection, by... and Jay S. Creswell; paper prepared for presentation at the 14th annual conference of the Canadian Highway Safety Council, Victoria, B.C., May 6-8, 1968. Ann Arbor, Univ.of Mich.Hwy.Saf.Res.Inst. var.paged. charts. In English and French.

Description of "a generalized model...to consider the effectiveness of inspection systems (as measured by the number of faulty vehicles on the road) as a function of the expected lifetime of a component (like a taillight), the expected time for the owner to detect and repair a fault, and the kind of inspection system in being."

O'Day, James. A modeling approach to motor vehicle inspection, by... and Jay S. Creswell, Jr. [prepared] for presentation at the Winter annual meeting and Energy systems exposition, Pittsburgh, Pa., November 12-17, 1967 of the American Society of Mechanical Engineers. New York, Am.Soc.of Mech.Eng. 9p. chart. 67-WA/BHF-3. $1.50.

"An attempt to define systematically the parameters needed to evaluate inspection systems." The authors discuss factors determining vehicle condition and costs (administrative and owner) vs. inspection program levels and describe a study comparing defective vehicle lights in two cities, one with and one without an inspection program.

20712

O'Day, James. Periodic motor vehicle inspection and predictive analytical modeling, by...and Jay S. Creswell, Jr. HSRI Res., Oct. 1968 [entire issue] charts, table, bibl.

Extension of the authors' earlier works with model test and validation. Application to programs may indicate (1) emphasis on inspection of components which fail quickly and are repaired slowly, (2) consideration of "trade-offs between frequency and inspection efficiency", (3) improvement of vehicle condition through defect-detection devices which can alert owner to repair need or improved component reliability.

Operations Research. An investigation of used car safety: final report, by H. Eisner [and others] prepared for U.S. National Highway Safety Bureau, Contract FH-11-6522. Silver Spring, Md., June 30, 1968. 5v. charts, tables, bibl. Distributed by CFSTI (PB 179712-6).

v.1. Summary and program plan.- v.2. Qualitative evaluation.- v.3. Quantitative evaluation, pt.1. Technical considerations.- v.4. Quantitative evaluation, pt.2. Economic considerations.- v.5. Appendices.

"The basic approach adopted by ORI in this study can be summarized by the following brief set of steps: (a) Systems analysis and modeling to structure the problems, develop effectiveness and cost measures, establish and assess alternatives to determine the elements of an approved safety program, (b) Data collection to estimate the parameters defined in the preceding, (c) Description and assessment of the adequacy of current practices, including strengths and weaknesses, gaps to be filled, and problems in implementing NTMVS and NHS Act requirements."

Peat, Marwick, Livingston & Company. Highway safety management guidelines for state governments, prepared for U.S. National Highway Safety Bureau, Contract no.FH-11-6627. Washington, June 1968. 144p. charts, tables. Distributed by CFSTI (PB 179019).

Contents: Why guidelines?- The highway safety program structure.- Organizing for highway safety.- The management process in highway safety.- Measuring program efficiency and effectiveness.- Management information.

Appendix: Suggested program structure.- Suggested highway safety program structure.- Model legislation and executive order.

The periodic technical inspection of motor vehicles: an international survey. Intl.Rd.Saf.and Traf.Rev., Summer 1965, p.17-20+

Survey of nineteen countries with compulsory or voluntary motor vehicle inspection programs. Three detailed tables give information on types of inspection stations, categories of cars inspected, parts examined, and enforcement.

RCA Service Company. A design for periodic motor vehicle inspection. Camden, N.J. [1968?] 9p.
RCA proposal to conduct statewide PMVI program.

ABSTRACT - Ohio State staff personnel
prepared this manual to assist school bus
drivers in the State of Ohio to become
familiar with the transportation laws, to
acquaint them with the best known techniques
of school bus driving, and to impress upon
them the magnitude of their responsibilities.
Ten units include: (1) Introduction to School
Bus Driver Education, (2) Public Relations,
(3) Pupil Transportation Laws and Regulations
in Ohio, (4) Digest of Motor Vehicle Laws of
Ohio, (5) Bus Maintenance, (6) Driving
Fundamentals, (7) Defensive Driving, (8)
Safety and Emergency Procedures, (9) First
Aid, and (10) The Special Child. Most
sections in the units provide content,
orientation material, presentation
suggestions, and a summary. A glossary and
bibliography are included. (GEB)

PREFACE

The purpose of this manual is (1) to assist the school bus drivers in the State of Ohio to become familiar with the transportation laws enacted by the Ohio General Assembly and the transportation rules and regulations adopted by the State Board of Education, (2) to acquaint the drivers with the best known techniques of school bus driving and (3) to impress upon the drivers the magnitude of their responsibilities and the necessity to observe every safety precaution.

A combined effort by the personnel of the Transportation Section of the Division of School Finance and the Trade and Industrial Education Section of the Division of Vocational Education made the writing and publishing of this manual possible.

Special acknowledgment is given to the following individuals for their contributions:

I. **WRITERS:**

John Burkam, Supervisor, Foundation Section, State Department of Education

Dudley Lee, Coordinator of School Transportation, Area #17, State Department of Education.

Zygmont Rataiczak, Coordinator of School Transportation, Area #28, State Department of Education.

Robert Seward, Coordinator of School Transportation, Area #21, State Department of Education.

Roger Smith, Coordinator of School Transportation, Area #9, State Department of Education.

Robert Whisman, Consultant, School Bus Driver Education, Trade and Industrial Education Section, State Department of Education.

II. **CONSULTANTS:**

Harry F. Davis, Assistant Director, Trade and Industrial Education Section, State Department of Education.

Hanford L. Combs, Section Chief, Transportation Section, State Department of Education.

Roy W. Grossman, Supervisor, Transportation Section, State Department of Education.

20722

Consultants (cont.)

W. F. Stover, Consultant, Instructional Materials Laboratory (Ohio State University), State Department of Education.

III. ADVISORY COMMITTEE:

Walter Johnson, Transportation Director, Columbus City Schools, Columbus, Ohio.

William Lawless, Transportation Supervisor, Ironton City Schools, Ironton, Ohio.

Wilson Leatherman, Transportation Supervisor, Berea City Schools, Berea, Ohio.

Richard L. Miller, Transportation Supervisor, Switzerland of Ohio Local Schools, Woodsfield, Ohio.

Lloyd Pipes, Transportation Supervisor, Mount Vernon City Schools, Mount Vernon, Ohio.

Burnill F. Rouster, School Bus Driver Education Instructor, Toledo City Schools.

Verlin K. Smith, Bus Supervisor, Pike County Board of Education, Waverly, Ohio.

Adolph J. Somrack, Transportation Manager, Willoughby-Eastlake City Schools, Willoughby, Ohio.

Eugene Welker, Transportation Supervisor, Clermont Northeastern Local Schools, Batavia, Ohio.

Glenn C. Zietsma, School Bus Driver Education Instructor, Toledo City Schools, Toledo, Ohio.

Dr. Martin Essex, Superintendent of Public Instruction

Bryl R. Shoemaker, Director of Division of Vocational Education

UNIT I

INTRODUCTION TO SCHOOL BUS DRIVER EDUCATION

/ 20726

UNIT I

I. TOPIC

Introduction To School Bus Driver Education Program

II. ORIENTATION

A. The content in this unit will include course objectives, class rules and regulations, history of Ohio Driver Education Program, national and Ohio school transportation history, Ohio's program for organization and line of responsibility for transportation, and the ten commandments of transportation safety.

B. It is important to become familiar with the above mentioned items, using them as a foundation to proceed.

III. PRESENTATION

A. Purposes and Objectives of Program

1. Improve the quality and efficiency of school bus driving in Ohio
2. Improve and promote safety procedures
3. Reduce fleet maintenance costs by proper inspection and use of equipment
4. Cause the bus driver to realize his extensive responsibilities and duties
5. Provide adequate training for every bus driver in Ohio

B. Class Rules and Regulations

1. One hundred per cent attendance is required during this training course

   a. Make-up of a missed class is possible in case of an emergency
   b. This must be done through special arrangements with the instructor

2. Score of 75% or better is required on final written examination to pass the course
3. Certificates will be issued upon successful completion of the course based on the above regulations.

   a. A certificate for display in the bus
   b. A billfold certificate will be issued

4. If a class member does not successfully complete the course; he may re-take the training when it is offered.

   a. If he holds a valid Ohio school bus driver's license, the unsuccessful completion of this course does not invalidate said license.
   b. A new driver must successfully complete the Basic Course sometime within the first year of driving.

5. Class sessions will start and end on time.

   a. Ten minute break each hour if schedule permits
   b. Smoking regulations of host institution shall be followed.
   c. Class members are to bring manuals and supplies to each meeting.
   d. Intervals between class sessions should be used for study, review, and practice.

C. History of Ohio's School Bus Driver Education Program

The first historical facts, that can be located, dealing with school bus driver education occurred at Ohio State University in May of 1949. These facts grew from a conference conducted by Dr. Robert Reese and his aide, George Brandon, from the Ohio State University of Trade and Industrial Education.

The main topics discussed at the conference were vehicle maintenance, rules and regulations of the road, and driver education. The conference participants were selected from personnel who had a keen interest as well as experience in school transportation. The participants consisted of School Administrators, Safety Engineers, Driver Education Consultants, and Law Enforcement Officers.

The program remained in a discussion phase with no record of additional conferences or planning until January of 1963 when Trade and Industrial Services in conjunction with Ohio State University and the State Department of Education, established the job classification of School Bus Driver Education Consultant. The State Department of Education had this to say:

> "A few short years ago pupil transportation was a small auxiliary service to be tacked on the school budget and easily administered by spending a few hours with some of the drivers. Today the cost of transportation is a major item in the school budget and administrators spend many hours struggling with the problems that accompany this growth."

School district reorganization and consolidation plus the migration of masses of people to the suburbs have created problems of larger rural school attendance areas. To the bus driver, this means more students to transport, more daily miles

20728

to travel, and more daily time to devote to the transportation program. No longer should a person be employed to do this job unless some training in the skills and knowledge of driving a school bus has been acquired. The bus driver is hauling truly a most precious cargo.

With the above mentioned thoughts in mind the State Department of Education hired James Provost on February 1, 1963, as transportation consultant under the Division of Vocational Education. Mr. Provost had experience in bus driving, driver education, bus fleet supervision, and school administration.

After studying programs in other states and placing into operation an advisory committee, material and literature were reviewed and an outline, composed of units that the committee thought should be included in Ohio's manual of instruction, were developed.

Mr. Provost completed the final pre-publication copy of the manual and it was used in two pilot programs to test the instruction time involved and the value of the material. A pilot program was held first in a large city school, then one in a predominately rural school to determine if the content was practical for all types of schools. Necessary revisions to the manual were then made, based on the results of the pilot programs, and the manual went to press late in 1963. While the manual was being printed, an instructor's guide was developed to aid the instructors in the sequence of instruction and in timing the units of instruction. The first official classes began early in January of 1964 at Bedford City School in Cuyahoga County and Willoughby-Eastlake School in Lake County. From this date forward Ohio could offer a practical program for the school bus driver.

1. Pre-Employment Course consisting of 36 hours
2. Basic Course consisting of 18 hours
3. Advanced Course consisting of 30 hours

D. History of Pupil Transportation in The United States and Ohio

The first laws governing the transportation of children to school in the United States were enacted in the year 1869. The city of Quincy, Massachusetts provided the first transportation facilities for students in 1874.

Figure 1

Ohio's pupil transportation program was initiated in Ashtabula County in 1892, with a proposal to consolidate some of the school districts. Kingsville Township, Ashtabula County, and other small districts in the area decided to transport their students to a village school rather than build a new school building.

20729

FOREWORD

The food service industry has undergone changes as far reaching as those experienced by other industries. Improved refrigeration and freezing processes have introduced new ideas in food production and service. The trend is toward centralized food service through use of the commissary and assembly line techniques, microwave ovens, and rapid steam-cooking equipment. Automation has placed new demands on food preparation personnel. These changes, coupled with an ever-expanding population, have given the food service industry a new look.

Food preparation and service, at present, call for a greater degree of skill and a more technical knowledge. Schools at the secondary level and post high school programs must provide the education and training prerequisite for entry into the industry.

The purpose of this manual is to provide a suggested plan to be used by school officials in developing a training program in quantity food preparation. The guide is designed for use by instructors as an aid in developing a course of study. It is *not* for student use. It is a tool to be used only by persons charged with the responsibility of planning the program.

The original guide under this title was published as Circular No. 526 by the U.S. Office of Education in 1958. This revised edition was developed by the Education Department of the National Restaurant Association under contract with the U.S. Office of Education. The manuscript was prepared by John J. MacAllister, Director, School of Hotel and Restaurant Administration, Oklahoma State University.

Consultants who reviewed the manuscript and suggested many improvements were: Kathryn Bruce, Education Department, National Restaurant Association, Chicago; Hilda Watson Gifford, Council on Hotel, Restaurant and Institutional Education, San Francisco; Vincent Galvin, Director, Food Service Course, Edison Technical School, Seattle; and Edward Martin, Director, Educational Services, Chicago and Illinois Restaurant Association, Chicago.

The Division of Vocational and Technical Education expresses appreciation for the cooperation and the assistance of the food service industry in the modernizing of this publication.

WALTER M. ARNOLD
Assistant Commissioner for Vocational and Technical Education

2048

In order to legalize this procedure, a bill was introduced into the General Assembly of Ohio, and it became a law on April 17, 1894. The first state-wide law providing for pupil transportation was passed by the General Assembly on April 5, 1898.

Ohio's pupil transportation program has undergone many significant changes. The first type of vehicles to be used were horse drawn and, in some cases, the board owned the wagon and hired a driver with a team. The most common practice, however, was to contract with an individual for the service of a driver, conveyance, and team of horses.

Figure 2

The above vehicle is approximately a 1903 Wayne school car. It was 12 feet long and transported 12 passengers. This vehicle was heated by a corn cob heater.

From these early horse-drawn vehicles to our most modern buses, there has been a constant increase in the number of students being transported to school for their education. The most rapid growth, however, came with the development of the automobile and the building of hard-surfaced roads. At the present time in the State of Ohio, the implementation of the Fair Bus Bill, the reorganization of school districts, people moving to the outlying suburbs, the manufacturing of larger buses, and the building of better roads have all expanded the transportation area of our school districts.

20730

With the increased square miles of area to be covered, and the use of larger buses, the responsibilities of the school officials and particularly the school bus drivers have grown tremendously.

Some interesting growth patterns can be revealed by comparing the data listed in Table 1:

	School Year 1941-42	School Year 1961-62	School Year 1968-69
1. No. of Buses	6,800	8,908	10,864
2. No. of Pupils Transported	290,000	795,411	1,211,651
3. Total Cost for Ohio	6,998,150	23,309,583	40,554,879

The growth of the total transportation program has brought about many changes in the state, county, and local school's educational programs. Bus service can no longer be classified as an auxiliary service but has become an integral part of the total school program. The number of people involved and the amount of money expended greatly increases the demand for better trained transportation supervisory personnel and school bus drivers. Throughout the years of pupil transportation five general objectives have emerged in the organization and administration of pupil transportation. These are:

a. Safety
b. Economy
c. Adequacy
d. Efficiency
e. Equality

E. Sample School Organizational Chart

20731

1. The bus driver should evaluate his position within the program.
2. Teamwork is the only answer.

F. **The Bus Drivers' Ten Commandments of Safety:**

1. Know and obey the traffic laws and regulations set forth in "Ohio Rules and Regulations."
2. Obey all traffic control devices as though they were an actual flesh-and-blood officer.
3. Know that the STOP sign means stop.
4. Do not cross railroad tracks when warning lights, bell, or other warning devices indicate the immediate approach of a train. A slow freight may screen a fast passenger train. The driver must be certain that all tracks are clear before he proceeds.
5. Stay in the correct lane of traffic and heed the yellow line no-passing zones.
6. Be positive that the vehicle is mechanically safe.
7. Drive defensively, always expect the other driver or pedestrian to do the unexpected.
8. Avoid sudden starts and stops.
9. Never take undue risks.
10. Always be courteous in the respect for the rights, lives, and property of others.

IV. SUMMARY

A. Objectives of the program should constantly be kept in mind.
B. The school bus driver should objectively evaluate himself.
C. The necessary action to correct shortcomings or weaknesses should be taken by the driver.
D. Drivers should ask questions as the program moves along.

1. There is no such thing as a stupid question.
2. If any driver doesn't know he should ask.

E. Drivers should know the laws and regulations, and Ten Commandments; and abide by them.
F. Everyone will learn something if each driver's attitude is such that he will give the ideas that are to be presented a try.

20732

UNIT II

PUBLIC RELATIONS

9 20733

UNIT II

I. TOPIC

Public Relations

II. ORIENTATION

"No man is an island unto himself." There are few occupations left in our world which permit a person to work independently. Certainly the business of education recognizes that only when human beings work together can they hope to do a satisfactory job in educating the young people of our nation.

A. Cooperation Is A Must!

1. Parent with teachers.
2. Teachers with administrators.
3. Administrators with supervisors.
4. Bus drivers with all of the above.
5. Professional ethics are a must!

Figure 3

B. Working Together - How well we work together, one with another, depends to a large extent on our relations with other human beings. Human relations is that vital key which can unlock the doors of:

1. Cooperation
2. Effective communication
3. Success of the job to be done

20734

C. **Bus Driver's Relationship to the Total School Program**

The transportation of pupils to and from school is a far more important part of the total school program than many people would realize. The driver's duties, for example, necessitate that he work in close harmony with:

1. Pupils
2. Fellow school officials
3. Parents
4. Members of the community

D. **Successful Relationships** - His success in these relationships with the people of each of these above areas can have a tremendous effect upon the continued support of the community for its schools. The driver is, then, a public relations agent for the schools.

E. **The School Bus Driver Is a Teacher on Wheels**

III. **PRESENTATION**

A. **The Driver and the Pupils** - Although it is generally understood that the chief responsibility of the school bus driver is to transport the pupils to and from school in a safe and effecient manner, there are other important aspects of the job which should not be overlooked.

1. He can "set the educational tone" of the day for the student.

   a. First contact student has with a school official in the morning.
   b. Last contact at night.

Figure 4

2. He must maintain good control of the students while they ride the bus. This is a must for safe school bus operation. Some guiding principles for the driver which will assist him in maintaining good student behavior and control are:

   a. Recognize his responsibilities and identify himself as a staff member of the school system.

20735

b. Know the policies and regulations relating to his duties.
c. Explain to the pupils at beginning of school term the rules which govern their conduct on the bus.
d. Conscientiously obey rules governing drivers; setting a good example will create respect.
e. Teach respect by showing respect.

(1) Students should address the driver by proper name; such as, Mr. Brown.
(2) The bus driver should address the student by proper name.

f. Let students know obedience is expected; correct in positive terms, such as "Do this!"
g. Take a personal interest in each pupil.
h. Listen and observe carefully for trouble making situations.
i. Prevention forestalls real trouble when conditions causing trouble are found, correct them as soon as possible.
j. Assigning seats aids student control and in cases of vandalism, aids in the investigation.
k. Delay punishment when angered and upset.
l. A problem child on the bus may be a problem in the classroom; a talk to teacher or principal might help. (Check board policy for procedure.)
m. Give authorized punishment where it is merited; in most cases, a warning is sufficient buy don't threaten unless prepared to carry out the threat.
n. Private personal contact or discussion with problem student may help - do not humiliate.
o. Accept each child as he is and try to help him to greater achievements.

3. The three "F's" in dealing with pupils are:

a. Be friendly but not familiar
b. Be firm but not unduly strict.
c. Be fair and not partial.

4. Be courteous to all students; a "good morning", a "goodbye", and a smile go a long way.
5. Word of warning, however, friendliness can be carried too far; the driver should never joke with students to the extent that he becomes overly familiar.

a. The driver is not a student; the student does not expect him to act like a student.
b. Pupils will not respect the adult who tries to be "one of the crowd."

20736

6. Proper behavior is learned; not inherited. Teach pupils proper school bus behavior at the beginning of the school year. "As the twig is bent, so grows the tree."

   a. Orientation by classroom teacher.
   b. Orientation through school assemblies.

B. The Driver and Other School Officials

1. As a member of the educational team for a given school district, it is extremely important that cooperation and mutual respect exist between all members of the team.

   a. Classroom teachers
   b. Bus drivers
   c. Supervisors
   d. Custodians
   e. Administrators
   f. Secretaries

   } all have an important job to be done.

2. Respect other school officials' positions and responsibilities.
3. Avoid criticizing other school personnel to students, parents, other drivers, and to the public.
4. Utilize resources of fellow team members.

   a. Problem child on bus

      (1) Talk with his classroom teacher; she may be having the same problem.
      (2) A guidance counselor may have been working with the child and can give some valuable suggestions as to how to correct this pupil.

   b. Possible handicap pupils - the deaf, partially blind, epileptic, other emotional problems, see Unit X.

      (1) See principal's or supervisor's advice (Board policy).
      (2) Classroom teacher or health nurse may help.

   c. The bus driver may have discovered some health or emotional problems which should be shared with other school personnel.
   d. No one team member sees the whole child; but together, a far better picture is obtained.

20737

C. **The Driver and Parents** - "Each morning I loan you my most precious possession. Please drive carefully and do everything you can to insure he will come home at night; well and healthy." A MOTHER'S PRAYER

1. Parents of pupil passengers on each bus expect a safe trip to and from school each day for their children. (World's most precious cargo)

2. *Driver should create a feeling of security in the minds of these parents by establishing and maintaining safe driving procedures and effective pupil control on his bus.*

Figure 5

3. Parents hear pupils talk about their experiences on the school bus, and all too often, may form opinions as to the driver and the school on this basis.
4. The driver should become acquainted with as many parents as possible.

   a. Driver should get to know parents under pleasant conditions-- it may help later when he needs their cooperation and help on a disciplinary matter.
   b. Driver should make parents feel that he is genuinely interested in their comments and suggestions.

5. Time schedules are important to parents.
6. Pitfalls to be avoided for all school personnel.

   a. Never argue with parents.
   b. Never lose temper when discussing matters with parents.
   c. Never attempt to discuss or handle pupil problems with a parent through the open door of the bus.

      (1) Make arrangements to have the parents contacted.
      (2) Refer the parent to the person in charge of the transportation program for a conference.

7. If the driver has built good human relations with the parents of his passengers, much can be accomplished when the driver needs parental help and cooperation.

20738

D. **The Driver and the Community** - Every business and industry is constantly concerned about its "public image." Any company which prints the name of the firm on the side of a truck, trailer, or auto must realize that the company's image is created in the minds of thousands of motorists on the highways each day. So it is with a school bus.

A school bus driver is moving a yellow and black sign, thirty-five feet long and eight feet wide, down the community's highways each morning and evening.

Figure 6
Do you advertise well?

1. The driver must create a favorable image for the school district by:

   a. Being a careful and alert driver.
   b. Observing courtesy on the highways.
   c. Observing local and state traffic laws and regulations on the streets and highways.
   d. Driving a clean "sign" (bus). The vehicle may not be new, but it must be clean, well-kept, and in good mechanical condition.

2. Some citizens in a community have no other contact with the local school except the school bus, which they see each day as it travels up and down their street or road. The driver, the vehicle, and the pupils on that particular bus route are their only bases to judge the school system.

IV. SUMMARY

It is difficult to over-emphasize the importance of human relations. A good over-all school system must have a good transportation program. A poor transportation program will penalize an otherwise sound educational system. The school bus driver plays a key role in the success or failure of the transportation program. He must be constantly aware of his human relations with:

UNIT III

PUPIL TRANSPORTATION LAWS AND REGULATIONS IN OHIO

18 / 19 20741

PUPIL TRANSPORTATION LAWS AND REGULATIONS IN OHIO

Introduction

Pupil transportation in Ohio is governed by the Revised Code of Ohio, by Regulations adopted by the State Board of Education, and by policy adopted by school district boards of education.

A Board of Education is limited to powers expressly granted by statute and those necessary to carry into effect the powers expressly granted. Where discretionary powers are vested by statute in a Board of Education, such discretion is limited only by Judicial Review in case of fraud or abuse of discretion (1928 OAG 1714).

These Regulations have been adopted by the State Board of Education with the advice and consent of the Director of Highway Safety.

UNIT III

SECTION ONE

I. TOPIC

Transportation Responsibilities of the State Agencies

II. STATE DEPARTMENT OF EDUCATION

A. Construction and Design of School Buses (Sec. 4511.76(A) O.R.C.)

The State Department of Education shall adopt and enforce standards of construction, design and equipment of all school buses owned and/or operated by public school districts or under contract with a public school district. (See Ohio School Bus Minimum Standards)

NOTE: All other buses are regulated by the Director of Highway Safety. (See Sec. 4511.76(B) O.R.C.)

B. Operating Regulations (Sec. 4511.76(A) O.R.C.)

The State Department of Education shall adopt and enforce regulations which govern pupil transportation administration and operation procedures.

NOTE: All other buses are regulated by the Director of Highway Safety. (See Sec. 4511.76(B) O.R.C.)

C. Fiscal Responsibilities (Sec. 3317.051 O.R.C.)

1. The State Board of Education shall determine by formula the total amount of money approved for each district in which the transportation meets the regulations prescribed by it to secure an efficient and economical program of pupil transportation. (Sec. 3327.012 O.R.C.)
2. The State Board of Education shall adopt a formula for assistance to eligible districts for the purchase of school buses. (Sec. 3317.07 O.R.C.)

D. Area Coordinator (Transportation)

1. The Area Coordinator (Transportation) has the following responsibilities:

   a. Designate collection points (Sec. 3327.01 O.R.C.)
   b. Establish routes, schedules, and utilization of equipment that has been recommended by each board of education to whatever extent is feasible. (Section 3327.011 O.R.C.)

III. COUNTY BOARD OF EDUCATION, CITY AND EXEMPTED VILLAGE SUPERINTENDENTS

A. The County Board or City or Exempted Village Superintendent shall provide annual physical examinations for school bus drivers. (Sec. 3327.10 O.R.C.)

20743

B. The County Board or City or Exempted Village Superintendent shall issue a drivers' certificate upon determining that each school bus driver and substitute driver has met the requirements as established by the Ohio Revised Code and these regulations. (See School Bus Driver)

C. The County Board of Education or City or Exempted Village Superintendent may revoke such certificate:

1. When the school bus driver fails to meet the requirements established by these regulations. (See School Bus Driver)
2. When a driver is found guilty of improper conduct or has failed to notify the authorities of all traffic violations and convictions; or has failed to comply with any laws of the State of Ohio, Regulations of the State Board of Education, or policies of the school district of employment.

D. The county, city or exempted village superintendent shall provide at least one (1) annual safety workshop for transportation personnel.

IV. LOCAL, CITY AND EXEMPTED VILLAGE SCHOOL BOARD RESPONSIBILITIES

A. District Boards of Education:

1. Are responsible for the operation of the school transportation program. The Board of Education may delegate the authority for direct control to the superintendent or other administrative employee.
2. Shall provide transportation for all pupils so crippled that they are unable to walk regardless of the distance to a school where the State Board of Eduction prescribes minimum standards. (Sec. 3327.01 O.R.C.)
3. Shall provide transportation for all resident elementary children who live more than two miles from the public school to which they are assigned or to the non-public school to which they attend. (Sec. 3327.01 O.R.C.)
4. Shall recommend to the Area Coordinator (Transportation) routes, schedules, and utilization of transportation equipment. (Sec. 3327.011 O.R.C.)
5. Shall adopt a time schedule and put in force no later than ten days after the beginning of the school term. (Sec. 3327.01 O.R.C.)

B. District Boards of Education may:

1. Provide transportation for high school pupils. (Sec. 3327.01 O.R.C.)
2. Provide transportation for any elementary or high school pupils residing any distance. (Sec. 3327.01 O.R.C.)
3. Pay a parent or guardian in lieu of transporting an eligible pupil when the board deems such transportation impractical. (Sec. 3327.01 O.R.C.)
4. Procure accident insurance on school buses. When carried by the Board, the amount of liability insurance shall not exceed five hundred thousand dollars. (Sec. 3327.09 O.R.C.)

20744

5. Designate depots to gather pupils for transportation purposes. If the board designates such a depot, they shall provide a shelter. (Sec. 3327.03 O.R.C.)
6. Maintain turn-around points. (Sec. 3327.12 O.R.C.)
7. Make cooperative agreements with recreation commissions for the use of school buses to transport students taking part in summer recreation programs. (OAG 67-081-1967)
8. Assess a fee, not to exceed the actual cost, for transportation to and from established educational exhibits and programs during summer months, Saturdays, and holidays.
9. Use buses for summer or auxiliary service programs for resident pupils sponsored by district boards of education.

NOTE: Transportation operational expense records must be maintained for sections 8 and 9 above. Such expenses are not reimbursable through state foundation monies.

10. Permit the use of school buses in the event of civil emergency.

C. **Boards of Education shall not:**

1. Transport pupils to or from any school which practices discrimination against any person on the grounds of race, color, religion, or national origin. (Sec. 3327.01 O.R.C.)
2. Pay a parent more than the state average cost per pupil for transporting pupils in the previous school year, when the board pays the parent or guardian in lieu of transporting a pupil eligible for such service. (Sec. 3327.01 O.R.C.)
3. Transport pupils residing within another district without that school district's written consent. (Sec. 3327.05 O.R.C.)
4. Transport pupils to a school which does not meet the minimum standards prescribed by the State Board pursuant to Division (D) of Section 3301.07 of the Revised Code. (Sec. 3321 O.R.C.)

D. **District Boards of Education Are Not Required to Provide Transportation For:**

1. Non-public pupils who attend a school which requires more than 30 minutes of direct travel time as measured by a school bus from the collection point to the pupil's school of attendance. (Sec. 3327.01 O.R.C.)
2. Pupils where it is impractical to provide such service with a school bus. (Sec. 3327.01 O.R.C.)
3. Pupils, when in the judgment of such board of education and confirmed by the State Board of Education, such transportation is unnecessary or unreasonable. In determining the necessity for transportation, availability of facilities and distance to school shall be considered. (Sec. 3327.01 O.R.C.)

20745

UNIT III

SECTION TWO

I. TOPIC

Transportation Personnel Responsibilities

II. THE TRANSPORTATION ADMINISTRATOR (SUPERINTENDENT OR SUPERVISOR)

A. A transportation administrator may be the superintendent, local superintendent, principal, transportation supervisor or any other person designated by the Board of Education to administer the transportation program. The Board of Education may delegate the administration, but not its legal responsibilities for, pupil transportation.

B. The transportation administrator shall provide safe school buses by:

1. Assuring that all school buses meet or exceed the "Ohio School Bus Minimum Standards" in effect at the time of purchase.
2. Providing a quality, continuing maintenance program.
3. Providing for the pre-inspection and completion of Form T-30 (O.D.E.) for all school buses before the annual Ohio State Highway Patrol inspection.
4. Assuring that all school buses are presented for inspection.
5. Providing for regular safety inspections and correcting immediately all deficiencies noted.

C. Is responsible for recommending to the Board of Education the names of qualified applicants for employment.

D. Shall see that all school bus drivers are instructed as to routes, time schedules, duties, laws, regulations, and school district policies related to pupil transportation.

E. Is responsible for seeing that all drivers meet the requirements of the laws of Ohio and Ohio Department of Education regulations before driving a bus with pupils on board. He shall make arrangements for the basic school bus driver's education program. (See School Bus Driver)

F. He shall maintain a school district map or route description system indicating all routes, pick-up points, names of students by bus by stop, the grade and school of attendance, and a route time schedule.

G. He shall administer the transportation policies and procedures relating to pupil behavior.

20746

H. He shall, in the case of city and exempted village school districts, provide for one (1) annual safety workshop for transportation personnel. Local school district transportation administrators shall require the transportation personnel to attend one (1) annual county sponsored safety workshop.

I. He shall be responsible for maintaining accurate records of:

1. Vehicle inventory
2. Daily miles traveled
3. Students transported
4. Annual operating costs by vehicles for the regularly scheduled trips.

J. He shall maintain accurate record of annual miles and costs for non-routine use of school buses.

K. He shall provide all information as required by the Ohio Department of Education.

III. THE SCHOOL BUS DRIVER

A. To be employed as a school bus driver the following requirements must be met:

1. Be at least 21 years of age.
2. Be of good moral character.
3. Be physically qualified as determined by an annual physical examination meeting the criteria established by Ohio Department of Education Form T-8.
4. Prior to testing by the Ohio State Highway Patrol, be trained in the operation of a school bus and have a knowledge of the Transportation Laws and Regulations.
5. Hold a current Ohio Chauffeur's License marked "School Bus Operator".
6. Hold a current bus driver's certificate issued by the County Board of Education or City or Exempted Village Superintendent.
7. Shall be required to satisfactorily complete the State Department of Education's Basic School Bus Driver Education Program within the first year of employment as a school bus driver.
8. Attend all safety workshops and meetings as required by district administration.

B. It is recommended that boards of education not employ any person as a school who has passed his 65th birthday.

C. No person shall be employed as a bus driver who is addicted to alcohol, narcotics or other drugs of a sedative nature.

D. The bus driver shall not use or permit the use of tobacco while pupils are on the bus.

E. The use of stimulants, sedatives or any other substance which will affect the bus driver's judgment and driving ability during his routes is prohibited.

20747

UNIT III

SECTION THREE

I. TOPIC

Operational Regulations

II. SCHOOL BUS OPERATIONS AND DRIVING PROCEDURE

A. The school bus driver shall make a daily inspection to determine if the bus is in safe operating condition.
The following items should be checked:

1. Air Brakes - (a) Drain water from air reservior tanks
   (b) Air pressure indicators
2. Brake Pedal - Travel on hydraulic brake systems
3. Steering
4. Tires and Wheel Lugs
5. Engine Oil Level - Must not be below "add" mark
6. Radiator Coolant Level
7. Emergency Equipment
8. Heaters and Defrosting Equipment (seasonal)
9. Lights
10. Instruments and Gauges
11. Horn
12. Windshield Wipers and Washers
13. Interior Cleanliness
14. Glass Areas - Clear vision to front, sides and rear

B. All items checked and found deficient shall be reported to responsible authority. Mechanical defects shall be reported in writing.

C. In no event shall a bus be driven backward on school grounds while children are being loaded or unloaded.

D. When departing from the loading area, buses shall maintain a safe interval. No passing shall be permitted in the loading area.

E. Bus drivers shall maintain a distance of 300 feet behind any preceding moving vehicle while traveling on the highway at normal speed.

F. School buses operating on divided highways or highways with four or more traffic lanes shall receive and discharge all school children on their residence side of the highway. (Sec. 4511.75(C) O.R.C.)

G. Before receiving and discharging pupils on the highway, the bus shall be driven to the right side of the paved or traveled portion of the roadway and brought to a full stop.

20748

H. The bus driver shall be the only operator of the service entrance door. The door shall not be opened to load or unload pupils until traffic has cleared the bus or come to a complete stop in all directions.

I. Warning flasher lights shall be used to prewarn other motorists of the intention of the bus to stop for the singular purpose of loading or unloading pupils. The lights shall remain in operation during the total time the bus remains stationary.
Warning flasher lights shall not be used:

(1) When stopped for railroad grade crossings
(2) While stopped on traveled highway used for loading and unloading pupils at school locations
(3) At turn arounds

J. Driver shall not use service door control to activate warning flasher lights. Door must remain in complete "locked" position while bus is in motion.

K. Four-way hazard lights may be used at bus turn arounds.

L. The bus shall not be started in motion until after pupils who have been discharged from the bus have reached a place of safety on their residence side of the road. (Sec. 4511.75(D) O.R.C.)

M. The driver shall use the established route and make stops as designated by the board of education or the administrator who is authorized to designate such stops.

N. The driver shall operate the bus on the approved time schedule and shall wait for pupils if running ahead of schedule.

O. School buses shall be brought to a stop before crossing railroad grade crossings and while so stopped, the driver shall listen through an open door or open window and look in both directions along the track. He shall not proceed until safe to do so.
The driver shall cross only in such gear of the vehicle that there will be no necessity for changing gears during the crossing. (Sec. 4511.63 O.R.C.)

P. The school bus driver shall require silence of all pupils at all railroad crossings. All school bus drivers shall obey all state and local traffic laws.
SPEED (Sec. 4511.21 O.R.C.)
No person shall operate a motor vehicle, trackless trolley, or streetcar in and upon the streets and highways at a speed greater or less than is reasonable or proper, having due regard to the traffic, surface, and width of the street or highway and any other conditions, and no person shall drive any motor vehicle, trackless trolley, or streetcar in and upon any street or highway at a greater speed than will permit him to bring it to a stop within the assured clear distance ahead.

20749

Introduction

The food service industry has undergone many changes and substantial expansion during the past two decades. These changes have created an unprecedented increase in the demand for well-trained personnel in food service. New production methods, improved refrigeration, pre-prepared frozen foods, mixes, and new types of equipment have caused the industry to look to the schools for trained workers.

In the past, outstanding chefs, cooks, and bakers, trained under the European apprenticeship system, were the main supply source. American hotel and restaurant operators experienced little difficulty in staffing their kitchens with distinguished food artists. Young Americans interested in becoming chefs could train under the tutelage of master craftsmen.

During the 1920's European-trained workers were beginning to be in short supply. Two distinct factors contributed to this shortage:

1. Immigration restrictions under the quota system limited the number of persons admitted to this country as potential citizens, and the aftereffects of World War I drastically curtailed the employment of many Europeans.
2. Hotel and restaurant operators, accustomed to obtaining qualified food preparation people from abroad, gave little thought to the need for programs to train American youths and adults for careers in the industry.

Neither food service operators nor educators gave much thought to the problem. Consequently, the importance of establishing training programs for food workers was neither fully recognized nor explored.

Generally, European-trained chefs believed that the apprenticeship system was the only way to prepare qualified cooks. Because this type of training for foods personnel was not popularly accepted in our country, apprenticeship programs in the food preparation field were not very successful and little was done to promote them.

An awareness on the part of hotel and restaurant operators of the growing shortage of European-trained chefs and cooks caused no little concern. Where were they to find the skilled food workers to meet their future needs?

A few farsighted leaders in the field advocated establishing organized vocational education programs in public schools. Outstanding proponents of this school of thought were Herman A. Breithaupt,[1] August Forester,[2] and Paul Muellet.[3] These leaders sought and gained the support of local school boards and were able to initiate food service training programs in public schools and post-high-school educational institutions.

As a result of the successful operation of these and similar programs, the food service industry began to realize that educational programs could produce the required skilled personnel. Consequently, public school systems were urged to develop and expand food service training.

The Council on Hotel, Restaurant and Institution Education—a membership organization composed of educators and industry representatives—and the Statler Foundation have actively supported and promoted the establishment of education for the food service industry. The National Restaurant Association and The American Hotel-Motel Association, working through their educational departments, have encouraged public school systems to establish food service training programs. Hotel and restaurant operators, as well as allied industry people, have done much to elevate the prestige or status of food service careers. Many hotel, restaurant, and allied firms have stimulated young people to seek careers in the food service industry by establishing scholarships.[4]

---

[1] Herman A. Breithaupt established a foods training program at Chadsey High School in Detroit, Mich., in 1939.

[2] August Forester set up one of the first food programs at Washburne Trade School in Chicago, Ill.

[3] Paul Muellet organized a program at the Edison Technical School in Seattle, Wash.

[4] The Council on Hotel, Restaurant and Institution Education, Statler Hall, Ithaca, N.Y., publishes a bulletin listing available scholarships.

2050

The maximum speeds for school buses are:

1. 20 MPH in school zones (during restricted hours).
2. 25 MPH inside corporations, except on state routes, through highways outside business districts and alleys.
3. 35 MPH on state routes or on through highways within municipalities outside business districts.
4. 50 MPH on controlled-access highways and expressways within municipal corporations (day or night).
5. 55 MPH on freeways outside municipal corporations (day or night).
6. 15 MPH on alleys within municipal corporations.

Section 4511.22 O.R.C.

No person shall operate a vehicle, trackless trolley, or streetcar at such a slow speed as to impede or block the normal and reasonable movement of traffic, except when reduced speed is necessary for safe operation or to comply with law.

Q. A school bus shall not be refueled while the engine is running.

R. The driver shall not leave the bus until the brakes are set, the engine stopped and the ignition key is removed.

III. TRAFFIC REGULATION

A. No school bus shall be stopped, or shall be turned so as to proceed in the opposite direction, upon any curve or upon the approach to or near the crest of a grade, where such vehicle cannot be seen by the driver of any vehicle approaching from either direction within 500 feet. (Sec. 4511.37 O.R.C.)

B. The school bus driver shall permit other vehicles to pass when a line of traffic accumulates at the rear of the bus. (Sec. 4511.75(A) O.R.C.)

C. A school bus shall not be parked within the limits of the highway right-of-way. (Sec. 4511.66 O.R.C.)

IV. PUPIL BEHAVIOR

A. While riding on a school bus, reasonable conversation is permissible and may be regulated by the driver.

B. The driver shall be in charge of the bus at all times and shall be responsible for order. He should not exclude a pupil from the bus. The driver shall report the unmanageable pupil to the proper authority. Disorderly conduct shall be sufficient reason for refusing transportation service to any pupil.

20750

C. Whenever it becomes necessary to refuse a pupil transportation, the school authorities shall notify the parents of such refusal with a full explanation. Until such time as the school authorities have received assurance from the parents of future good conduct on the part of the pupil and the bus driver has been so advised, the driver shall not permit the pupil to board the bus.

V. SCHOOL BUS ACCIDENT REPORTING

The bus driver shall report any accident involving a school bus to the police agency within whose jurisdiction the accident has occurred and to the superintendent of schools.

The superintendent of the school district whose bus was involved in an accident shall report such accident on Department of Education Form T-10 within fifteen days from the time of the accident.

A copy of each report shall be retained in district file for a period of five years.

Definition of Motor Vehicle Accident

(a) Any incident or occurrence involving a school bus operated by or under contract to a school district which results in a fatality, an injury, or damage to any motor vehicle or property.

(b) Any action taken by a bus driver employed by a school district which contributes directly to any fatality, injury or damage to any motor vehicle or property.

VI. LOADING AND UNLOADING AT SCHOOL FACILITIES

A. When it is necessary to load or unload pupils off the school grounds, the bus shall be stopped and positioned so that pupils do not cross the road to get to or from the bus.

B. All warning flasher lights shall be turned off while loading and unloading at the school building in order that traffic may proceed without interference.

C. Bus drivers shall remain on the bus while pupils are loading and unloading.

D. Pupils waiting to board buses shall be supervised by school authorities.

VII. SCHOOL BUS STOPS

The board of education shall approve all bus stops. School bus stops shall be limited so far as possible. Pupils may be required to walk to a designated bus stop.

VIII. PUPIL LOAD

Pupils may be assigned seats. The number of pupil standees shall not exceed 10% of the number seated.

20751

IX. NON-ROUTINE USE OF SCHOOL BUSES

A. The regulations governing non-routine use of buses apply to vehicles owned and operated by boards of education or under contract to a board of education. The regulations pertain to summer use of buses as well as during the regular school year.

B. Trip Permit
City, exempted village and local superintendents shall issue a trip permit for each co-curricular use of a school bus. The permit shall provide the following information: (1) date of the trip; (2) destination of trip; (3) purpose of the trip; (4) name of the school district; (5) driver's name; (6) bus registration number; (7) total miles of trip; (8) superintendent's signature.

C. School buses may be used to transport pupils to and from any event that is a planned part of the classroom or the educational program. Expenses may be paid from the general fund.

D. School buses may be used to transport participating pupils to and from any co-curricular activity programs approved by the district boards of education. Pupil participants living on the most direct route to the activity from the school may be picked up and discharged as far as is practical. These expenses shall not be paid from the general fund.

E. Each event that requires the use of more than five school buses to transport participants to and from a co-curricular activity shall require a resolution by the district board of education.

F. School buses shall not be used for pleasure trips.

G. School buses shall not be used to transport spectators, either student or adult.

H. Adults may be transported to assist teacher on educational trips, if approved by the superintendent.

I. Students may not be transported to observe college or professional games - i.e., football team, band, etc.

J. Buses shall not be used for combination trips such as taking students to a museum in the morning and to view a football contest in the afternoon.

K. No pupil charge may be made for transporting pupils in any school bus to and from regular day classes and other co-curricular trips on school days. This applies equally to board-owned buses and privately owned buses operated under contract with a board of education.

20752

OHIO PUPIL TRANSPORTATION REGULATIONS

DEFINITIONS

Area Coordinator (Transportation)

A representative of the Ohio Department of Education who serves as liason in matters relating to pupil transportation and other services.

Civil Emergency

An unnatural condition resulting from an act of nature such as a flood or earthquake, from a catastrophe such as an explosion or fire or from a riot, etc., which threatens the safety of the general public.

Co-Curricular Activity

Any event or program approved by the board of education.

Four-Way Hazard Lights

Flashing signals used to warn other motorists of the presence of a vehicular traffic hazard requiring unusual care in approaching, overtaking or passing.

Non-Routine Use of School Buses

Every use of school buses other than the usual day to day transportation of pupils to and from school.

O.A.G.

Ohio Attorney General

O.D.E.

Ohio Department of Education

O.R.C.

Ohio Revised Code

Warning Flasher Lights

Alternately flashing signals used to inform other motorists of the school bus driver's intent to stop for the purpose of receiving or discharging school children.

STATE LAWS PERTAINING TO PUPIL TRANSPORTATION

SEPARATE FACILITIES FOR MENTALLY RETARDED CHILDREN

3313.88

The board of education of any school district may establish separate schools or facilities for the instruction of mentally retarded children and may:

(A) Expend school funds in the establishment of such schools or facilities;

(B) Provide for the transportation of any such pupils to and from the schools or facilities established under this section;

(C) Contract with the child welfare board, the board of county commissioners, or any municipal corporation to provide training for mentally retarded children upon whatever terms the contracting parties agree upon for the division of the cost of maintaining and operating the schools or facilities for such pupils. (127 v H568. Effective 9-16-57.)

Board may contract for transportation of mentally retarded pupil to public school in another district, but not to private school.

TRANSPORTATION OF PUPILS; EXCESS COST FROM FEDERAL FUNDS

3327.01

In all city, exempted village, and local school districts where resident elementary school pupils live more than two miles from the school for which the state board of education prescribes minimum standards pursuant to division (D) of section 3301.07 of the Revised Code and to which they are assigned by the board of education of the district of residence or to and from the non-public school which they attend the board of education shall provide transportation for such pupils to and from such school except when, in the judgment of such board, confirmed by the state board of education, such transportation is unnecessary or unreasonable.

In all city, exempted village, and local school districts the board may provide transportation for resident high school pupils to and from the high school to which they are assigned by the board of education of the district of residence or to and from the non-public high school which they attend for which the state board of education prescribes minimum standards pursuant to division (D) of section 3301.07 of the Revised Code.

In determining the necessity for transportation, availability of facilities and distance to the school shall be considered.

A board of education shall not be required to transport elementary or high school pupils to and from a non-public school where such transportation would require more than thirty minutes of direct travel time as measured by school bus from the collection point as designated by the coordinator of school transportation, appointed under section 3327.011 of the Revised Code, for the attendance area of the district of residence.

20755

Where it is impractical to transport a pupil by school conveyance, a board of education may, in lieu of providing such transportation, pay a parent, guardian, or other person in charge of such child, an amount per pupil which shall in no event exceed the average transportation cost per pupil, such average cost to be based on the cost of transportation of children by all boards of education in this state during the next preceding year.

In all city, exempted village, and local school districts the board shall provide transportation for all children who are so crippled that they are unable to walk to and from the school for which the state board of education prescribes minimum standards pursuant to division (D) of section 3301.07 of the Revised Code and which they attend. In case of dispute whether the child is able to walk to and from the school, the health commissioner shall be the judge of such ability.

When transportation of pupils is provided the conveyance shall be run on a time schedule that shall be adopted and put in force by the board not later than ten days after the beginning of the school term.

A district receiving a payment pursuant to division (B) of section 3317.02 of the Revised Code is not eligible for reimbursement of transportation operating costs or eligible for school bus purchase subsidy payment pursuant to section 3317.06 of the Revised Code, except for transporting children who are crippled and for transporting pupils attending non-public schools.

The cost of any transportation service authorized by this section shall be paid first out of federal funds, if any, available for the purpose of pupil transportation, and secondly out of state appropriations, in accordance with regulations adopted by the state board of education.

No transportation of elementary or high school pupils shall be provided by any board of education to or from any school which in the selection of pupils, faculty members, or employees, practices discrimination against any person on the grounds of race, color, religion, or national origin. (132 v S 451. Effective 2-29-68. 132 v H 823, H1; 131 v S 365)

3327.011

Coordinators of school transportation shall be appointed according to provisions of section 3301.13 of the Revised Code to assure that each pupil, as provided in section 3327.01 of the Revised Code, is transported to and from the school which he attends in a safe, expedient, and economical manner using public school collection points, routes, and schedules.

In determining how best to provide such transportation, where persons or firms on or after April 1, 1965, were providing transportation to and from schools pursuant to contracts with persons or agencies responsible for the operation of such schools, a coordinator or the board of education responsible for transportation in accordance with section 3327.01 of the Revised Code shall give preference if economically feasible during the term of any such contract to the firm or person providing such transportation.

20756

The boards of education within the county or group of counties shall recommend to the coordinator of transportation routes, schedules, and utilization of transportation equipment. The coordinator, upon receipt of such recommendations, shall establish transportation routes, schedules, and utilization of transportation equipment, following such recommendations to whatever extent is feasible. The appeals from the determination of the coordinator shall be taken to the state board of education. (132 v H 455. Effective 12-11-67. 131 v S 365)

DESIGNATION OF DEPOTS

3327.03

The boards of education of city, exempted village, and local school districts may by resolution designate certain places as depots from which to gather children for transportation to school, when such districts provide transportation. The places designated as depots shall be provided with a shelter and be made comfortable during cold and stormy weather.

TRANSPORTATION OF NONRESIDENT PUPILS

3327.05

The board of education of any school district shall not provide transportation for any pupil who is a school resident of another school district unless the board of the district of the pupil's residence has given its written consent thereto. If the board of any school district files with the state board of education a written complaint that transportation for resident pupils is being provided by the board of another school district, contrary to this section, the state board of education shall make an investigation of such complaint. If the state board of education finds that transportation is being provided contrary to this section it may withdraw from state funds due the offending district any part of the amount that has been approved for transportation pursuant to section 3317.051 of the Revised Code. (126 v 288. Effective 10-1-56.)

SCHOOL BUSES AND DRIVERS

Purchase of School Buses; Terms; Bidding

3327.08

Boards of education of city school districts, exempted village school districts, local school districts, joint high school districts, and joint vocational schools may purchase on individual contract school buses and other equipment used in transporting children to and from school and to other functions as authorized by the boards of education, or the boards may, at their discretion, purchase such buses and equipment through whatever system of centralized purchasing is established by the state department of education for such purpose, provided that state subsidy payments shall be based on the amount of the lowest price avialable to the boards by either method of purchase. No such board of education

20757

shall be deprived of any form of state assistance in the purchase of said buses and equipment by reason of purchases of said buses and equipment on an individual contract. Boards of education, in the purchase of said buses and equipment on individual contract shall make such purchases on the following terms:

(A) Not less than one-fourth of the purchase price thereof shall be paid in cash.

(B) Not less than an additional one-fourth of the purchase price thereof shall be paid within one year from the date of purchase.

(C) Not less than an additional one-fourth of the purchase price thereof shall be paid within two years from the date of purchase.

(D) The remaining balance of the purchase price thereof shall be paid within three years from the date of purchase. Such boards may issue the notes of the school districts signed by the president and the clerk of the board, and specifying the terms of the purchase including deferred payments as provided in this section, which notes may bear interest at a rate not exceeding four per cent per annum. In the legislation under which such notes are authorized, the board shall make provision for levying and collecting annually by taxation amounts sufficient to pay the interest and the specified portion of the principal. Revenues derived from local taxes or otherwise, for the purpose of providing transportation of children or for defraying the current operating expenses of such district, may be applied to the payment of such interest and the retirement of such notes.

The purchase of school buses shall be made only after competitive bidding in accordance with divisions (A), (B), (C), (D), (E), (F), (H), and (I) of section 3313.46 of the Revised Code. Separate and independent bids shall be received with respect to the chassis and body type, and shall state that the buses, when assembled and prior to delivery, comply with the safety regulations of the department of education adopted by and with the advice and consent of the director of highway safety pursuant to section 4511.76 of the Revised Code and all other pertinent provisions of law. (131 v H 760. Effective 11-8-65.)

INSURANCE ON BUSES AND PUPILS

3327.09

The board of education of each school district may procure liability and property damage insurance covering each school bus or motor van and accident insurance covering all pupils transported under the authority of such board. This insurance shall be procured from a recognized insurance company authorized to do business of this character in the state, and such accident insurance shall provide compensation for injury or death to any pupil caused by any accident arising out of or in connection with the operation of such school bus, motor van, or other vehicle used in the transportation of school children, in such amounts and upon such terms as may be agreed upon by the board and the insurance

20758

company. The amount of liability insurance carried on account of any school bus or motor van shall not exceed five hundred thousand dollars. Such insurance coverage may be effected in one or more recognized insurance companies authorized to do business in this state. (130 v H 268. Effective 9-16-63.)

QUALIFICATION OF DRIVER

3327.10

(A) No person shall be employed as driver of a school bus or motor van, owned and operated by any school district or privately owned and operated under contract with any school district in this state, who has not received a certificate from the county board of education of the county in which he is to be employed, in case such person is employed by a school district under the supervision of the county board, or by the superintendent of schools, in case such person is employed by the board of a city or exempted village school district, certifying that such person is at least twenty-one years of age and is of good moral character and is qualified physically and otherwise for such position. The county board or the superintendent, as the case may be, shall provide for an annual physical examination that conforms with regulations adopted by the state board of education of each driver to ascertain his physical fitness for such employment. Any certificate may be revoked by the authority granting the same on proof that the holder has been guilty of improper conduct, failing to file all traffic convictions with the county board or the superintendent, or neglect of duty and the said driver's contract shall be thereby terminated and rendered void.

(B) No person shall be employed as driver of a school bus or motor van not subject to the regulations of the department of education pursuant to division (A) of this section who has not received a certificate from the school administrator or contractor certifying that such person is at least twenty-one years of age, is of good moral character, and is qualified physically and otherwise for such position. Each driver shall have an annual physical examination which conforms to the state highway patrol regulations, ascertaining his physical fitness for such employment. Any certificate may be revoked by the authority granting the same on proof that the holder has been guilty of improper conduct, failing to file all traffic convictions with the school administrator or contractor, or neglect of duty and such driver's contract shall be thereby terminated and rendered void.

(C) Any person who drives a school bus or motor van must give satisfactory and sufficient bond except a driver who is an employee of a school district and who drives a bus or motor van owned by the school district. (130 v H 161. Effective 10-14-63. 129 v 1003)

The Outlook for the Food Service Industry

Large increases in population, coupled with greater per capita income, have brought about an accelerated demand for persons in food service. At present the food service industry is ranked as the Nation's fourth largest.

Reports published by the United States Bureau of Census [5] indicate that there were approximately one-half million establishments serving food in 1963.[6] Commercial establishments accounted for more than 50 percent of the three million persons employed in the industry. Food sales by commercial establishments in 1963 totaled $18.5 billion, an increase of 20 percent over 1958. Population expansion, higher income levels, and increased leisure time have exerted pressure on the food service industry.

If the Nation's population continues to expand at the present rate, the food service industry will experience a similar growth rate. Industry expansion will stimulate the development of more efficient food preparation techniques. Improved equipment and techniques will simplify production processes and make possible greater productivity. As a consequence, the demand for well-trained food workers will continue to grow. One of the major sources of these workers will be graduates of commercial food service programs conducted by technical and vocational high schools and other post-high-school educational institutions.

Objectives of the Suggested Program

This manual is designed to assist the instructor in planning the course content for a quantity foods preparation training program; the broad objectives and specific goals of the program are identified as follows:

Broad Objectives

1. To determine the range of training required for personnel in food preparation.
2. To suggest the relative emphasis that should be placed on the various areas of instruction.
3. To encourage the development of occupational competency and high standards of workmanship.
4. To enhance the status and dignity of the food service industry.
5. To encourage the development of reliable workers and good citizens.
6. To foster students' understanding of the functions and functional relationships of jobs in the food service industry.

Specific Goals

1. To teach the fundamental skills associated with the preparation and service of food.
2. To teach the necessary related subject matter pertaining to food preparation.
3. To teach safe methods of work performance.
4. To teach the value of orderliness and preplanning.
5. To develop an appreciation of accuracy and the use of standards in production.
6. To develop through demonstration and practice an understanding of the use and care of equipment.
7. To develop an appreciation of sanitation and hygiene, as both personal and public trusts.

Suggested Program of Instruction

Successful training courses in quantity food preparation vary in content and method of operation. This outline has been prepared for use as a guide in developing a program of instruction in food service training. It does not limit or define in absolute terms what should or should not be included in developing a quantity food preparation program.

Educational and professional authorities generally agree that the minimum length of a basic course in quantity food preparation should be 2 years. A 3-year course, where circumstances permit, is preferable. The curriculum outline suggested in this manual may be adapted to a 2- or 3-year course as part of a high school program or a specialized trade program.

School authorities, responsible for starting a new or reorganizing an existing program of in-

[5] U.S. Bureau of Census, 1963 Census of Business.
[6] Hospitals, schools, colleges, and other public and private institutions where food is served are included in this estimate.

MAINTENANCE OF SCHOOL BUS TURN-AROUND POINTS

3327.12

The board of education of a city, exempted village, or local school district may maintain school bus turn-around points. At the request of such a board, a municipal corporation may maintain turn-around points on municipal roads; the township trustees may maintain turn-around points on township roads; and the county commissioners may maintain turn-around points on county roads.

The municipal corporation, township trustees, or county commissioners may also, at the request of a board of education, maintain turn-around points located on private property after an investigation by such board of education has determined that such maintenance is necessary for the use of such private property as a turn-around point for school buses. Such board of education may provide the cost of the materials utilized for any such maintenance. (131 v H 782. Effective 11-5-65)

Section 4503.17

(A) No school bus as defined in division (E) of section 4511.01 of the Revised Code is required to pay the annual license tax provided for in section 4503.02 of the Revised Code or to apply for or display registration plates, provided: the school bus complies with the requirements of sections 4511.76 to 4511.77, inclusive, of the Revised Code.

(B) The owner of a school bus, other than a board of education, which is used as a school bus during the school year under a contract with a board of education may, upon proper application for registration and the payment of a license fee of twenty-five dollars, use such bus during summer vacation periods to transport children and their authorized supervisors to and from any camping function sponsored by a nonprofit tax-exempt, charitable, or philanthropic organization. The application for registration of such bus shall be accompanied by:

(1) An affidavit, prescribed by the registrar of motor vehicles and signed by the owner of such bus, stating that such bus is to be used exclusively, during the summer months, to transport school children to and from any school function or to transport children and their authorized supervisors to and from any camping function sponsored by a nonprofit, tax-exempt, charitable, or philanthropic organization,

(2) A certificate from the state highway patrol stating that such bus is safe for operation in accordance with such standards as are prescribed by the state highway patrol.

20760

TRAFFIC LAWS --OPERATION OF MOTOR VEHICLES

Section 4511.01

Definitions

(E) "School bus" means every bus designed for carrying more than nine passengers which is owned by a public, private, or governmental agency or institution of learning and operated for the transportation of children to or from a school session or a school function, or owned by a private person and operated for compensation for the transportation of children to or from a school session or a school function; provided "school bus" does not include a bus operated by a municipally owned transportation system, a mass transit company operating exclusively within the territorial limits of a municipal corporation, nor a common passenger carrier certified by the public utilities commission unless such bus is devoted exclusively to the transportation of children to and from a school session or a school function.

LOCAL TRAFFIC REGULATIONS

Section 4511.07

Sections 4511.01 to 4511.78, inclusive, 4511.99 and 4513.01 to 4513.37, inclusive, of the Revised Code do not prevent local authorities from carrying out the following activities with respect to streets and highways under their jurisdiction and within the reasonable exercise of the police power:

(J) Regulating traffic in reference to school buses.

No ordinance or regulation enacted under divisions (D), (E), (F), (G), (I), or (J) of this section shall be effective until signs giving notice of such local traffic regulations are posted upon or at the entrance to the highway or part thereof affected, as may be most appropriate.

VEHICLES REQUIRED TO STOP AT GRADE CROSSINGS

Section 4511.63

The operator of any motor vehicle or trackless trolley, carrying passengers, for hire or of any school bus, or of any vehicle carrying explosives or flammable liquids as a cargo, or such part of a cargo as to constitute a hazard, before crossing at grade any track of a railroad, shall stop such vehicle or trackless trolley, and while so stopped he shall listen through an open door or open window and look in both directions along the track for any approaching train, and for signals indicating the approach of a train, and shall proceed only upon exercising due care after stopping, looking and listening as required by this section and upon proceeding, the operator of any such vehicle shall cross only in such gear of the vehicle that there will be no necessity for changing gears while traversing such crossing and the operator shall not shift gears while crossing the tracks.

20761

This section does not apply at street railway grade crossings within a municipal corporation, or to abandoned tracks, spur tracks, side tracks, and industrial tracks when the public utilities commission has authorized and approved the crossing of such tracks without making the stop required by this section.

SCHOOL BUSES

Regulations Concerning School Buses

Section 4511.75

(A) The driver of a vehicle upon a highway outside the limits of a municipal corporation, upon meeting or overtaking from either direction any school bus which has stopped on the highway for the purpose of receiving or discharging any school child, shall stop the vehicle not less than ten feet from such school bus and shall not proceed until such school bus resumes motion, or until signaled by the driver to proceed.

(B) Where a highway has been divided into two roadways as set forth in section 4511.35 of the Revised Code a driver of a vehicle proceeding on one roadway of said highway need not stop when approaching a school bus which has stopped on the other roadway of said highway for the purpose of receiving or discharging any school child. The driver of any vehicle proceeding on the same roadway of said highway as the school bus shall comply with division (A) of this section.

(C) School buses operating on divided highways or on highways with four or more traffic lanes shall receive and discharge all school children on their residence side of the highway.

(D) No school bus driver shall start his bus until after any child who may have alighted therefrom has reached a place of safety on his residence side of the road.

REGULATIONS FOR OPERATION OF SCHOOL BUSES

Section 4511.76

(A) The department of education by and with the advice and consent of the director of highway safety shall adopt and enforce regulations relating to the construction, design, equipment, and operation of all school buses owned and operated by any school district or privately owned and operated under contract with any school district in this state. When such buses are privately owned and operated under contract with any school district in this state, these regulations shall, by reference, be made a part of any such contract with a school district. Every school district, its officers and employees, and every person employed under contract by a school district shall be subject to such regulations.

20762

Any officer or employee of any school district who violates any such regulation, or who fails to comply with regulations in any contract executed by him on behalf of a school district, is guilty of misconduct and subject to removal from office or employment. Any person operating a school bus under contract with a school district who fails to comply with any such regulation is guilty of a breach of contract, and such contract shall be canceled by the responsible officers of such school district.

No person shall operate such a school bus within this state in violation of the regulations of the department of education. No person, being the owner thereof or having the supervisory responsibility therefor, shall permit the operation of such a school bus within this state in violation of the regulations of the department of education.

(B) The department of highway safety shall adopt and enforce such regulations as relate to the safety of the construction, design, equipment, and operation of all school buses not subject to the regulations of the department of education pursuant to division (A) of this section. Such regulations shall be adopted pursuant to the provisions of Chapter 119. of the Revised Code.

No person shall operate such a school bus within this state in violation of the regulations of the department of highway safety. No person, being the owner thereof or having the supervisory responsibility therefor, shall permit the operation of such a school bus within this state in violation of the regulations of the department of highway safety.

(C) The department of highway safety shall adopt and enforce such regulations as relate to the issuance of a license under section 4511.763 of the Revised Code. Such regulations may relate to the moral character of the applicant; the condition of the equipment to be operated; the liability and property damage insurance carried by the applicant; the posting of satisfactory and sufficient bond; and such other rules and regulations as the director of highway safety shall deem reasonably necessary for the safety of the pupils to be transported.

SCHOOL BUS INSPECTION

Section 4511.761

The state highway patrol shall inspect every school bus to ascertain whether its construction, design, and equipment comply with the regulations adopted pursuant to section 4511.76 of the Revised Code and all other provisions of law.

The superintendent of the state highway patrol shall adopt a distinctive inspection decal not less than twelve inches in size, and bearing the date of the inspection, which shall be affixed to the outside surface of each side of each school bus which upon such inspection is found to comply with the regulations adopted pursuant to section 4511.76 of the Revised Code. The appearance of said decal shall be changed from year to year as to shape and color in order to provide easy visual inspection.

20763

No person shall operate, nor shall any person being the owner thereof or having supervisory responsibility therefor permit the operation of, a school bus within this state unless there is displayed thereon the decals issued by the state highway patrol bearing a date of inspection prior to the fifteenth day of October in the calendar year in which the decals were issued, except for a bus licensed by the department of highway safety pursuant to section 4511.763 of the Revised Code which shall display decals bearing a date of inspection between the sixteenth day of July and the first day of September of the calendar year in which the inspection was made, but if a bus is purchased after the first day of September, it shall display decals bearing a date of inspection later than the date the bus is purchased and prior to the date of its use for the transportation of pupils.

LICENSING

Section 4511.763

No person, partnership, association, or corporation shall engage in the transportation of pupils to or from school, for profit, or enter into a contract with a board of education of any school district, without being licensed by the department of highway safety.

REGISTRATION OF SCHOOL BUSES

Section 4511.764

The superintendent of the state highway patrol shall require school buses, as defined in division (E) of section 4511.01 of the Revised Code, to be registered, in the name of the owner, with the state highway patrol on forms and in accordance with regulations as the superintendent may adopt.

When the superintendent is satisfied that the registration has been completed, he shall assign an identifying number to each school bus registered in accordance with this section. The number so assigned shall be marked on the front and rear of the vehicle in black lettering not less than six inches in height and will remain undhanged as long as the ownership of that vehicle remains the same.

No person shall operate, nor shall any person, being the owner thereof or having supervisory responsibility therefor, permit the operation of a school bus within this state unless there is displayed thereon an identifying number in accordance with this section.

20764

Section 4513.17 (C and D)

Flashing lights are prohibited on motor vehicles, except as a means for indicating a right or a left turn, or in the presence of a vehicular traffic hazard requiring unusual care in approaching, or overtaking or passing. This prohibition does not apply to the use of a flashing, oscillating, or rotating amber light on emergency vehicles, *** road service vehicles servicing or towing a disabled vehicle, traffic line stripers, snow plows, rural mail delivery vehicles, state highway survey vehicles, funeral escort vehicles, and similar equipment operated by the department or local authorities, nor to vehicles or machinery permitted by section 4513.11 of the Revised Code to have a flashing red light.

Except a person operating a public safety vehicle, as defined in division (E) of section 4511.01 of the Revised Code, or a school bus, no person shall operate or move upon any public street or highway any vehicle or equipment which has a flashing red or a flashing combination red and white light, or any vehicle or equipment which has an oscillating or rotating red light or a combination red and white oscillating or rotating light. This section shall not prohibit the use of warning lights required by law or the simultaneous flashing of turn signals on disabled vehicles.

DISPLAY OF WARNING DEVICES ON DISABLED VEHICLES

Section 4513.28

(A) Whenever any motor truck, trackless trolly, bus, commercial tractor, trailer semi-trailer, or pole trailer is disabled upon the traveled portion of any highway or the shoulder thereof outside of any municipality, or upon any freeway, expressway, thruway, and connecting, entering or existing ramps within a municipality, at any time when lighted lamps are required on vehicles and trackless trolleys, the operator of such vehicle or trackless trolley shall display the following warning devices upon the highway during the time the vehicle or trackless trolley is so disabled on the highway except as provided in division (B) of this section:

(1) A lighted fusee shall be immediately placed on the roadway at the traffic side of such vehicle or trackless trolley, unless red electric lanterns or red reflectors are displayed.

(2) Within the burning period of the fusee and as promptly as possible, three lighted flares or pot torches, or three red feflectors or three red electric lanterns shall be placed on the roadway as follows:

(a) One at a distance of forty paces or approximately one hundred feet in advance of the vehicle;

(b) One at a distance of forty paces or approximately one hundred feet to the rear of the vehicle or trackless trolley except as provided in this section, each in the center of the lane of traffic occupied by the disabled vehicle or trackless trolley;

(c) One at the traffic side of the vehicle or trackless trolley.

20765

(B) Whenever any vehicle used in transporting flammable liquids in bulk, or in transporting compressed flammable gases, is disabled upon a highway at any time or place mentioned in division (A) of this section, the driver of such vehicle shall display upon the roadway the following warning devices:

(1) One red electric lantern or one red reflector shall be immediately placed on the roadway at the traffic side of the vehicle;

(2) Two other red electric lanterns or two other red reflectors shall be placed to the front and rear of the vehicle in the same manner prescribed for flares in division (A) of this section.

(C) When a vehicle of a type specified in division (B) of this section is disabled, the use of flares, fusees, or any signal produced by flames as warning signals is prohibited.

(D) Whenever any vehicle or trackless trolley of a type referred to in this section is disabled upon the traveled portion of a highway or the shoulder thereof, outside of any municipality, or upon any freeway, expressway, thruway and connecting, entering or exiting ramps within a municipality, at any time when the display of fusees, flares, red reflectors, or electric lanterns is not required, the operator of such vehicle or trackless trolley shall display two red flags upon the roadway in the lane of traffic occupied by the disabled vehicle or trackless trolley, one at a distance of forty paces or approximately one hundred feet in advance of the vehicle or trackless trolley, and one at a distance of forty paces or approximately one hundred feet to the rear of the vehicle or trackless trolley, except as provided in this section.

(E) The flares, fusees, lanterns, red reflectors and flags to be displayed as required in this section shall conform with the requirements of section 4513.27 of the Revised Code applicable thereto.

(F) In the event the vehicle or trackless trolley is disabled near a curve, crest of a hill, or other obstruction of view, the flare, flag, reflector, or, lantern in that direction shall be placed as to afford ample warning to other users of the highway, but in no case shall it be placed less than forty paces or approximately one hundred feet nor more than one hundred twenty paces or approximately three hundred feet from the disabled vehicle or trackless trolley. (130 H. 603)

UNIT IV

DIGEST OF MOTOR VEHICLE TRAFFIC LAWS OF OHIO

46/47 20767

STATE OF OHIO
JAMES A. RHODES
Governor

DEPARTMENT OF HIGHWAY SAFETY
WARREN C. NELSON
Director

BUREAU OF MOTOR VEHICLES
FRED RICE, Registrar

STATE HIGHWAY PATROL
R. M. CHIARAMONTE, Supt.

Digest of MOTOR VEHICLE LAWS OF OHIO

(REVISED SEPTEMBER 1969)

IMPORTANT: Your driver's license expires on your birthday, in the year indicated on the license!

20768

Dear Ohioan:

Good highways are necessary to transport Ohio-made products to the market to provide more and better jobs for Ohioans. Ohio is the transportation center of the nation. Our highways are the finest. As you drive on our fine highways you share with more than six million drivers the responsibility of being a safe and courteous driver.

By knowing and understanding the enclosed regulations and by being a cautious and careful driver you can help make Ohio highways the safest in the nation. Wear your safety belt at all times.

My very best wishes for a safe, accident-free driving record.

Sincerely,

James A. Rhodes

JAMES A. RHODES
Governor of Ohio

20769

struction, should ascertain the nature of the training course. They will want to consider the purpose of their particular course, the needs of the community, the available space and equipment, the type of students to be taught, and the time allotted to the program. Local planning should be in accord with State plans, developed by the State vocational education department, so that the program will be eligible to receive reimbursement from Federal vocational education funds.

Regardless of the type of program planned, it is essential that job functions and relationships be considered in each subject matter area. Students should be properly oriented so that they will understand the role each job plays as part of an organization.

The following subject-matter areas are included in this Curriculum Guide:

I. Basic Principles of Quantity Food Preparation.
II. Science Related to Food Preparation.
III. Mathematics Related to Food Preparation.
IV. English Related to Food Preparation.
V. Safety Instruction.

Presentation of Instructional Material

The subject-matter content outlined may be presented in several ways. Basic principles of food preparation can be taught according to:

1. Classification of foods, composition of foods, and/or the type of product.
2. Cooking procedure.
3. Production station or serving area.
4. Menu position.

It is imperative that instruction in preparing food in all categories be included regardless of which method is used. The main objective is to teach the basic steps of sound preparation methods rather than to familiarize the student with a large number of stations or jobs in the production area. It is more important for the student to understand fully the steps in broiling meats than to know the duties of the broiler cook. The latter specialization can be reserved for his internship in the food industry.

Outline of the Suggested Program of Instruction

The content suggested for each subject area has been classified into three phases of instruction and is outlined under the following columnar headings:

1. Essential learning (Skill and knowledge).
2. Scope of instruction (Suggested content).
3. Information (Technical and related).

Teaching materials (books, manuals, charts, films, and periodicals) are included in appendix A. Each item is numbered and the corresponding number is used to form the teaching materials list which follows each area of instruction.

This suggested outline neither limits the scope of instruction nor includes every possible unit which can be taught in quantity food preparation. The instructor will determine the specific topics and references which should be added in order to produce a complete, all-inclusive course of study in food service training.

266-894 O-68—2

2052

PRE-EXAMINATION

For the purpose of obtaining an Ohio Temporary Instruction Permit all persons are required to contact a driver license examination station and undergo a pre-examination. This examination consists of a vision test, a test of the applicant's knowledge of motor vehicle laws, and a sign test. Every applicant will be required to present evidence of correct date of birth either by a birth certificate or other legal documentary evidence. If under 18, applicant must first submit satisfactory evidence, by presentation of an official certificate, of having successfully completed a driver education course approved by the State Department of Education—or a driver training course approved by the Director of Highway Safety.

APPOINTMENTS FOR DRIVER EXAMINATIONS

All driver license examinations are conducted by the State Highway Patrol and consist of the following: (1) A test of your knowledge of the laws and rules for safe driving. (2) A test of your vision. (3) A test of your knowledge and understanding of road signs and traffic signals. (4) A test of your driving and parallel parking ability—and observance of regulating signals, signs and road markings.

Driver examinations are given by appointment only, in order to reduce the amount of time the prospective examinee must spend at the examining station. When an appointment to undergo a driver examination has been made, the prospective examinee must be punctual; and if it is found that due to unforeseen circumstances he is unable to appear at the appointed time, he shall notify the examination station or the Highway Patrol where the appointment was made. Please cancel appointments far enough in advance so that another examination time may be assigned.

A careful study of the following information will help you pass the examination and will improve your knowledge of the laws, road rules, signs and signals. No road examination will be permitted in an unsafe vehicle.

NOTE: Before and during the actual driving test follow the examiner's instructions. At no time will you be instructed to operate your motor vehicle in violation of any law or safe driving regulation.

EXEMPTIONS FROM EXAMINATIONS

TAXI CAB DRIVER who has a currently effective operator's license is exempt from a chauffeur's examination.

MILITARY OR NAVAL SERVICE PERSONNEL ON ACTIVE DUTY, and in possession of a driver's permit, when operating an official motor vehicle, in connection with such duty, is exempt from license requirements of this state. Also—when on furlough during period of active duty, and for 6 months after such duty—**provided** he had an active license prior to active duty.

Registrar may waive operator's or chauffeur's examination of any **honorably discharged military or naval personnel,** and without any mental or physical disability that would affect such driving—**providing** (a) he had an active license in this state at the time he commenced such service and (b) such application is made not more than 6 months following discharge.

MINIMUM AGE

The minimum age for a Temporary Permit or Operator License is 16 years. The application for a Temporary Permit or Operator's License of a person under 18 years of age must be signed by either parent, guardian or other person having custody—or when neither exists, by a responsible person who is at least 21 years of age.

Any negligence or willful or wanton misconduct of a minor under 18, when driving a motor vehicle upon a highway, shall be imputed to the person who has signed the application of such minor. Such person(s) shall be jointly and severally

20770

liable with such minor for any damages caused by such negligence or willful or wanton misconduct.

TEMPORARY INSTRUCTION PERMIT

An applicant must undergo and pass a pre-examination before he is permitted to obtain a temporary instruction permit. For details contact the nearest State Driver License Examining Station. Such temporary instruction permit, when granted and in the applicant's immediate possession entitles him to drive a motor vehicle upon any street or highway—and only when accompanied by a licensed operator or chauffeur, who is actually occupying a seat beside the driver. The permit is valid for a six-month period from date of issuance.

OUT-OF-STATE LICENSES

Any person having in his possession a valid out-of-state license recognized by the State of Ohio, is exempt from obtaining a Temporary Instruction Permit, but shall submit to the regular examination in obtaining an operator's or chauffeur's license in this state.

No person shall receive an operator's or chauffeur's license, or a motorcycle operator's endorsement of an operator's or chauffeur's license, unless and until he surrenders to the Registrar all valid licenses in his possession issued to him by another jurisdiction recognized by this state. All surrendered licenses shall be returned by the Registrar to the issuing authority, together with information that a license is now issued in this state. No person shall be permitted to have in his possession more than one valid license at any time. The Registrar may promulgate and enforce rules governing the use of such instruction permit.

PROBATIONARY LICENSE

A Probationary License shall be issued to persons between the ages of 16 and 21 years. The Registrar of Motor Vehicles shall revoke the Probationary License issued to any person—when such person (before reaching his 18th birthday) has been convicted, pleaded guilty, or adjudged in juvenile court, of having committed a total of three separate motor vehicle violations.

RESTRICTED LICENSE

The Registrar of Motor Vehicles—upon issuing an operator's or chauffeur's license, a motorcycle operator's endorsement, an operator's or chauffeur's license renewal, or the renewal of any other license issued under Chapter 4507. of the Revised Code—may, whenever good cause appears, impose restrictions suitable to the licensee's driving ability with respect to the type of or special mechanical control devices required on a motor vehicle, which the licensee may operate; or such other restrictions applicable to the licensee as the Registrar determines to be necessary.

Physical Disabilities

Persons who have physical disabilities; or those who must have attachments either to their person or on their motor vehicles—must have a Restricted Temporary Instruction Permit. Such permits are issued only after a pre-examination has been conducted, the disability determined, and attachments necessary for safe operation required. This may include persons who are of short stature and who need special equipment for driving.

CHAUFFEUR'S LICENSE

1. The Minimum age for a chauffeur's license is 18 years.
2. A chauffeur's license issued after an examination has been passed is valid for a period of three years from the last birthday, before such chauffeur license is issued.

20771

3. Chauffeur's licenses being renewed are valid for a period of three years from date of expiring chauffeur's license.
4. A 2-1/2" x 2-1/2" photograph is required. The picture must have been taken within thirty days of the time of the application for a chauffeur's license.
5. A valid operator's license may be converted to a chauffeur's license. The operator must take a complete driver examination including a special chauffeur's test.

MOTORCYCLES AND MOTORCYCLISTS

1. Motorcycle operators must have a special license. If the cyclist has no automobile driver's license, he must obtain a restricted motorcycle license costing $4.00 for four years. If he has an auto driver's license, his motorcycle permit may be added as an endorsement to it, also at a cost of $4.00 for four years.
2. The new law prohibits handlebars or grips more than 15 inches higher than the saddle; requires that both operators and passengers wear helmets and eye protectors approved by the director of highway safety; and demands that all motorcycles be equipped with rear-view mirrors and effective mufflers containing baffle plates.
3. Devices for producing excessive smoke or gas, and any equipment which permits oil or any other chemical to flow upon the exhaust pipe or muffler, are prohibited, as are muffler cutouts or by-passes which allow excessive noise.
4. Applicants for motorcycle operator licenses must give an actual demonstration of their ability to exercise ordinary and reasonable control in the operation of the cycle by driving it under the supervision of an examining officer. They must also pass tests on physical condition, understanding of traffic control devices, and knowledge of motor vehicle laws.
5. Motorcycles and bicycles are subject to the same rules and regulations as motor vehicles, in so far as practicable.
6. Every person riding a motorcycle or bicycle upon a roadway shall be governed by the same regulations—as if he were driving any vehicle. Every operator of a motor bike, motor scooter, motorcycle, or similar vehicle must be properly licensed under the Ohio Driver's License Law.
7. No motorcycle or bicycle shall be used to carry more persons at one time than the number for which it is designed and equipped.

YOUR LICENSE: A TRUST AND A FAITH

No person shall:

1. Display, or cause or permit to be displayed, or possess any operator's or chauffeur's license or temporary permit, knowing the same to be fictitious, or to have been canceled, revoked, suspended, or altered.
2. Lend to a person not entitled thereto, or knowlingly permit him to use any operator's or chauffeur's license or temporary permit, not issued to the person so displaying the same.
3. Display, or represent as one's own, any operator's or chauffeur's license or temporary permit, not issued to the person so displaying the same.
4. Fail to surrender to the Registrar of Motor Vehicles, upon his demand, any operator's or chauffeur's license or temporary permit, which has been suspended, canceled, or revoked.
5. Use a false or fictitious name, or give a false or fictitious address, in any application for an operator's or chauffeur's license or temporary permit.

It is unlawful to permit your car to be operated by:

1. A person who does not have a driver's license.
2. By the holder of a Temporary Instruction Permit when not accompanied by a licensed driver on the seat beside him.

20772

DRIVER LICENSE SUSPENSIONS

The trial judge of any court of record . . . . in addition to suspensions or revocations of licenses for periods of time not exceeding three years, and in addition to, or independent of, all other penalties provided by law or by ordinance . . . . shall impose a suspended jail sentence not to exceed six months, providing that imprisonment was not imposed for the offense for which the person was convicted.

No court shall suspend the first thirty days of suspension of license provided for under this section.

The violations for which a driver's license may be revoked or suspended are:

(A) Homicide by vehicle;

(B) Operating a motor vehicle while under the influence of intoxicating liquor or narcotic drug;

(C) Perjury or the making of a false affidavit, under Sections 4507.01 to 4507.39, inclusive, of the Revised Code, or any other law of this state, requiring the registration of motor vehicles, or regulating their operation on the highway.

(D) Any crime punishable as a felony under the motor vehicle laws of this state or any other felony in the commission of which a motor vehicle is used;

(E) Failing to stop and disclose identity at the scene of the accident when required by law to do so;

(F) Drag racing as defined in division (A) of Section 4511.25 of the Revised Code;

(G) Willfully eluding or fleeing a police officer.

Ohio's Point System Law

Within ten days after conviction or bond forfeiture of a person in a mayor's court or a court of record for any violation under the revised uniform traffic code, Section 4511.01 to 4511.78, inclusive, 4511.99 and 4513.01 to 4513.36, inclusive, or of any law or ordinance regulating the operation of vehicles, street cars, and trackless trolleys on highways, said court shall prepare and forward to the Bureau of Motor Vehicles abstracts of court records covering such conviction or bond forfeiture.

The Registrar, within ten days after receipt of such abstract, shall record the date of conviction or bond forfeiture and the number of points for each conviction or bond forfeiture based on the following formula:

(1) Violation of section 4507.38 or 4507.39 of the Revised Code or any ordinance prohibiting the operation of a motor vehicle while the operator's license is under suspension or revocation ..... **6 points**

(2) Violation of section 4549.04 of the Revised Code or any ordinance prohibiting the operation of a motor vehicle without consent of the owner .. **6 points**

(3) Homicide by vehicle ..... **6 points**

(4) Violation of section 4511.19 of the Revised Code or any ordinance prohibiting the operation of a motor vehicle while under the influence of alcohol or drugs ..... **6 points**

(5) Violation of section 4549.02 of the Revised Code or any ordinance requiring the driver of a vehicle to stop and disclose identity at the scene of an accident ..... **6 points**

(6) Violation of section 4511.02 of the Revised Code or any ordinance prohibiting the willful fleeing or eluding of a police officer ..... **6 points**

(6)

20773

(7) Any crime punishable as a felony under the motor vehicle laws of this state, or any other felony in the commission of which a motor vehicle was used ..... **6 points**

(8) Operating a motor vehicle in violation of a restriction imposed by the registrar ..... **2 points**

(9) Violation of section 4511.251 of the Revised Code or any ordinance prohibiting drag racing ..... **6 points**

(10) Violation of section 4511.20 of the Revised Code or any ordinance prohibiting the reckless operation of a motor vehicle ..... **4 points**

(11) Violation of any law or ordinance pertaining to speed ..... **2 points**

(12) All other moving violations pertaining to the operation of motor vehicles reported under this section except any violations under section 5577.01 to 5577.99, inclusive, of the Revised Code ..... **2 points**

Whenever the points charged against any person exceed five, the Registrar shall forward to such person a warning letter, listing the reported violations.

When any person has more than seven points charged against him, he shall be required to submit to a driver license examination or a physical examination, or both.

When the number of points against any person reaches 12 within a two-year period, the Registrar shall, advise the subject that his license will be suspended for a period of time, depending upon the number of prior suspensions under this statute—effective on the 20th day after the mailing of the suspension notice.

Exceptions:

Unless the licensee files a petition in the municipal court or county court—or in case the person is under the age of eighteen years, to the juvenile court—in the county where such person resides, agreeing to pay the costs of the proceedings and alleging that the licensee can show cause why his license should not be suspended. The court shall decide such issue as to whether the person is a habitual traffic law violator. **If the court finds from the evidence submitted that he is a habitual traffic law violator, then the court may:**

1. Uphold the suspension made by the Registrar.
2. Withhold the suspension, or a part thereof, and provide such conditions or probations as the court deems proper.

Any person whose license or permit or privilege to operate a motor vehicle has been suspended under this section, and who, during such suspension drives any motor vehicle, shall be fined not more than $500, or imprisoned not less than three days nor more than six months—**and no court shall suspend the first three days of any sentence provided under this section.**

SPEED RESTRICTIONS

Speed Limits

Automobiles may not be operated upon streets or highways at a speed either greater or less than is reasonable and proper, having due regard for the traffic, surface and width of the street or highway and of any other conditions then existing. **A driver must keep his vehicle under such control as to be able to bring it to a stop within the assured clear distance ahead.**

It shall be unlawful to drive at a speed exceeding:

(1) **15 miles per hour** in all alleys within a municipal corporation.

20774

(2) **20 miles per hour** when passing a school building or the grounds thereof during school recess and while children are going to or leaving school during the opening or closing hours. Also when appropriate signs giving notice of the existence of the school are erected—except, that on controlled-access highways and expressways, if the right-of-way line fence has been erected without pedestrian opening, the speed shall be governed by provision in paragraph (5) below. On freeways, if the right-of-way line fence has been erected without pedestrian opening, the speed shall be governed by provisions in paragraphs (8) and (9) below.

(3) **25 miles per hour** in all other portions of a municipal corporation, except on state routes, through highways outside business districts, and alleys.

(4) **35 miles per hour** on all state routes or through highways (which are not controlled-access highways) within municipal corporations outside business districts, except as provided in paragraphs (5) and (6) below.

(5) **50 miles per hour** on controlled-access highways and expressways within municipal corporations.

(6) **50 miles per hour** also on state routes within municipal corporations outside urban districts, unless a lower prima-facie speed is established.

(7) **60 miles per hour** during the daytime and **50 miles per hour during the nighttime** on highways outside of municipal corporations—**except** 50 miles per hour at all times . . . for operators of trucks and commercial tractors, which weigh in excess of 4000 pounds empty weight; also for school buses, street cars and trackless trolleys.

(8) **60 miles per hour at all times on freeways with paved shoulders inside municipal corporations**—**except** 50 miles per hour at all times for operators of trucks and commercial tractors weighing in excess of 4000 pounds empty weight, as well as school buses.

(9) **70 miles per hour at all times on freeways outside municipal corporations**—**except** 55 miles per hour for operators of trucks and commercial tractors weighing in excess of 4000 pounds, as well as school buses.

The State Director of Highways may set up or permit local authorities to set up speed zones of greater or lesser speed than these prima-facie speed limitations upon the basis of engineering and traffic investigations. Such studies must show that the prima-facie speed is greater or lesser than is reasonable or safe under the conditions found to exist at the locations to be designated as special speed zones. The greater or lesser speed, whichever is determined, shall be effective only when appropriate signs giving notice thereof are erected at these special speed zones.

Racing on Public Roads

No person shall participate in a drag race on a public road. A drag race is one which consists of operation of two or more vehicles from a point, side by side and at accelerating speeds in a competitive attempt to out-distance each other. Or the operation of one or more vehicles over a common selected course, from the same point to the same point, when timing is made of the participating vehicles involving competitive accelerations of speeds. Persons rendering assistance in any manner to such competitive use of vehicles shall be equally charged as the participants.

Speed Limits on Bridges

No person shall drive a motor vehicle over any bridge or other elevated structure, constituting a part of a highway, at a speed which is greater than the maximum speed that can be maintained with safety to such bridge or structure, when such structure is sign-posted.

Minimum Speed Limits

No person shall operate a vehicle at such a slow speed as to impede or block the normal and reasonable movement of traffic, except when reduced speed is necessary for safe operation or to comply with law.

Whenever the Director of Highways or local authorities determine, on the basis of an engineering and traffic investigation, that slow speeds on any part of a controlled-access highway consistently impede the normal and reasonable movement of traffic—the Director of Highways or such local authority may declare a minimum speed limit, below which no person shall operate a motor vehicle, except when necessary for safe operation or in compliance with law. (**No minimum speed limit established hereunder shall be less than 30 miles per hour**; nor effective until provisions relating to appropriate signs have been fulfilled and local authorities have obtained the approval of the Director of Highways.)

Speed Clocked By Radar—Arrest Without Warrant

A driver, who has been detected speeding by radar, or by any electrical timing device, **may be arrested until a warrant can be obtained** for such arrest. (Posted radar or other similar warning signs no longer required.)

SAFE DRIVING PRACTICES

When being overtaken and passed by another motor vehicle approaching from the rear you shall not increase your speed until completely passed by the overtaking vehicle.

When overtaking and passing another vehicle on a two lane highway, make certain of assured clear distance ahead, give audible signal to the vehicle to be overtaken, pass to left at safe distance, and be sure not to 'cut-in' too closely ahead of the overtaken vehicle.

The purpose of highways and streets being marked in lanes for traffic proceeding in the same direction is:

1. When the roadway is sufficiently wide to permit more than one line of traffic, lanes are marked to clearly divide the lines of traffic to more safely facilitate the flow. Slow traffic should travel in the extreme right lane.
2. To provide marked lanes for passing and other safety measures as required.

Whenever any roadway has been divided into three or more clearly-marked lanes, or wherever, within a municipal corporation traffic is lawfully moving in two or more substantially continuous lines in the same direction—a vehicle shall be driven, as nearly as practicable, entirely within a single lane or line of traffic—and shall not move therefrom until the driver has first made certain that such movement can be made with safety.

When entering a through highway you must yield the right-of-way to all vehicles on said through highway.

When making a left turn you must yield right-of-way to all vehicles approaching from the opposite direction.

When parked at a curb, the most important thing is to make certain the portion of the highway you are about to enter is free from oncoming traffic for a distance sufficient to allow you to safely enter that part of the roadway.

The meaning of the yellow line on the highway is: When the yellow line is in your lane do not pass. When there are double yellow lines, passing in either direction is prohibited.

ENTERING OR LEAVING A VEHICLE

Get into a vehicle from the curb side, when it is parked parallel at the curb of any street or highway, where there is even a small amount of traffic. Getting either into or out of a vehicle on the roadway side may cause sudden stops or collisions in the passing traffic.

20776

LIGHTS AND REQUIREMENTS

The minimum number of lights required on a motor vehicle operated at night are — Two head lights, one red tail light and white light so arranged as to illuminate the rear license plate.

1. The law requires you to dim your lights upon the approach of an oncoming vehicle.
2. Only one spot light is permitted on a vehicle and the beam must be directed to the right on the left side of the vehicle and not to exceed one hundred feet ahead.
3. Every vehicle must display headlights and tail light from one-half hour after sunset to one-half hour before sunrise, and at any other time when there is not sufficient natural light to render discernible persons, vehicles, and substantial objects on the highway.

When following a vehicle at night you should lower the beam of your light so as not to blind the driver ahead.

A driver's reaction to red flags, flares and fusees on a highway should be: Danger ahead — slow down and stop.

HIGH BEAM

TO BE USED IN OPEN COUNTRY EXCEPT WHEN APPROACHING ONCOMING CAR.

LOW BEAM

TO BE USED ON LIGHTED STREETS, WHEN FOLLOWING OTHER CAR, DRIVING IN FOG AND APPROACHING ONCOMING CAR.

PARALLEL PARKING TEST

This test is very important as it tests the applicant's judgment and ability to handle a motor vehicle. It is a known fact that a driver who can park will eliminate traffic congestion and accidents.

The following procedure should be used in parallel parking:

1. Stop even with and about a foot away from the car in front of the space where you are going to park.
2. Make sure that you will not interfere with oncoming traffic.
3. Turn steering wheel sharply right and back slowly towards the curb.
4. When your front wheels are opposite the rear bumper of the car ahead, quickly turn steering wheel to extreme left and back slowly to car behind.
5. Straighten out front wheels and pull into final parking position a few inches from curb allowing adequate clearance at both ends of car.
6. The test is presumed to be successfully completed when the driver has properly removed his car from within the parking zone.

20777

FIRST, and of greatest importance, remember that traffic may be approaching from the rear.

Step 1. Always look back and make sure that the road is clear, before even attempting to park.

PARKING

It is illegal to park upon the paved or main traveled part of a highway outside of a business or residence district.

Six places where it is illegal to park a motor vehicle.

1. In front of a public or private driveway.
2. Within ten feet of a fire hydrant.
3. Within twenty feet of a cross-walk at any intersection.
4. Within thirty feet upon the approach to any stop sign.
5. Alongside any vehicle stopping or parked at the edge or curb of a street.
6. Within one foot of another parked vehicle.

The law requires a rear vision mirror. If operator is deaf, two rear vision mirrors are required—one inside and one outside.

Area I

BASIC PRINCIPLES OF FOOD PREPARATION

Area I is concerned with helping the student develop an appreciation and understanding of sound food preparation methods and skills. This entails a knowledge of the physical facilities within the food preparation area as well as the various methods of cooking food. An understanding of the characteristics that constitute quality in raw and finished foods is also involved.

Every effort should be made to help the student realize that patrons of hotels, restaurants, and other eating establishments, who will be consumers of his product, expect to receive full value for their expenditures. The student trainees, therefore, should recognize the factors involved in preparation and service, such as quality, appearance, and palatability, which determine the acceptability of food.

The instructor should use every means to help the student appreciate the importance of correct food preparation methods if the resultant product is to be satisfactory. The student must also appraise himself as a professional food worker. He must realize that work habits and standards of cleanliness have an important bearing on the quality of the food he prepares, on his performance as a food worker, and on his job success.

Area I is divided into 13 subdivisions, each devoted to a given phase of cookery or a related process. The 13 subdivisions are:

A. Care and Operation of Kitchen equipment.
B. Meat Cutting.
C. Meat and Poultry Cookery.
D. Fish and Shellfish Cookery.
E. Sauces and Gravies.
F. Ground and Variety Meat Cookery.
G. Egg and Breakfast Dishes.
H. Soups.
I. Vegetable Cookery.
J. Salads and Sandwiches.
K. Breads, Pastries, Cakes, and Cookies.
L. Desserts.
M. Appetizers, Canapés, and Hors d'Oeuvres.

2033

What To Do If A Tire Blows Out

A blow-out when traveling at a high rate of speed is dangerous, especially if the driver does not know what to do and becomes frightened. First of all, do not jam on the brakes and do not throw out the clutch. Keep your foot off the accelerator and let the vehicle coast against the engine to stop. When the blow-out is a rear tire, sudden application of the brakes will set up a "tail-sway" difficult to control and the vehicle is likely to turn over. Various types of safety tires may well be considered as important accessories.

When Wheels Run Off Pavement

If a vehicle's wheels run off the pavement onto the berm or soft shoulder, do not try to jerk the wheels immediately back onto the road. Stop accelerating without throwing out the clutch. Allow the engine to slow the vehicle so that it can be pulled safely back onto the pavement.

When Rounding a Curve

Never apply the brakes while you are rounding a curve but apply them before entering it. You may accelerate slightly on the way out of the curve—this extra power will offset the side-thrust of centrifugal force. It is not possible to apply brakes safely while in the process of rounding a curve.

No Coasting

Never coast down a grade in neutral gear. Shift into second gear when going down a steep hill. Coasting not only causes quicker wear-out of the brakes, but increases the possibility of an accident.

Funeral Procession

The following requirements are necessary for vehicles traveling in a funeral procession in order to be recognized and given right of way by other traffic: Each vehicle in a funeral procession must have its headlights lighted and display a purple and white pennant, so as to be visible from any direction.

The Blind Person As A Pedestrian

Watch out for persons carrying white canes or white canes with red tips. The blind are the only pedestrians authorized by law to carry white canes and the law further provides that the blind carrying such canes, as well as those led by guide dogs, are to be given the right-of-way by every driver.

Walking Along Roadway

Persons walking along or upon the highway where sidewalks are not provided must face approaching traffic.

ACCIDENTS

In case of accident on a public road or highway the law requires you as a driver to stop, give your name and address, the name and address of the owner and registration number of the motor vehicle, to the injured person or any person involved in the accident or to a police officer at the scene. You must also display your driver's license or furnish satisfactory proof that you are licensed.

In case of an accident with an unoccupied or unattended motor vehicle you shall securely attach the information required to be given in writing, to a conspicuous place in or on the unoccupied or unattended motor vehicle which was struck.

The operators of all motor vehicles, including non-residents, when they become involved in an accident, resulting in the death or injury to a person or property damage in excess of $100.00, must within 30 days after such accident, file a written

20780

EXPRESSWAY/FREEWAY DRIVING ILLUSTRATED

The Traffic Movement

(1) Pick your lane—and stay with it. Observe and obey signs.

(2) Faster travel means that you'll need more room between you and the car ahead in case of emergency. Follow no closer than one car length for every 10 miles of speed. Pass lawfully and safely.

(3) Stay within the posted speed limit, but be careful that you don't become a traffic hazard by driving too slowly.

(4) Watch for signs noting changes in speed limits. A "slow zone" signals a a danger area.

Fatigue

Be on your guard against highway monotony. Drive with the window open; shift your gaze; play the radio and engage in light conversation to keep alert. Stop periodically to stretch your legs and have a cup of coffee, milk or a cold "soft" drink.

How to Get Off An Expressway

(1) Watch for advance signs for your proper turn-off and move to the correct lane.

(2) Decrease your speed and signal your intention of turning.

(3) Drive slowly, or stop if necessary, before you enter traffic on the cross highway.

Skidding

Precautions taken against skidding are much simpler than steering out of one. However, when a vehicle does go into a skid, take your foot off the accelerator (never apply brakes) and turn the steering wheel in the direction of the skid.

Weaving

Weaving in and out of traffic lanes is a dangerous habit practiced only by the exhibitionist, or the inexperienced or discourteous driver. It actually gains for the driver no more than a few seconds, and causes sudden stops, near sideswipes and irritation among other drivers. Stay in the proper traffic lane and overtake and pass other vehicles only when the roadway ahead is clear.

One-Arm Drivers

Proper control and handling of a vehicle is achieved only when both hands are on the steering wheel. The safety of all occupants of a car, should any road hazard or emergency appear, is very uncertain when the driver is steering with one arm only. It is said rather humorously, but it may well be a fact, that "One-arm drivers are usually headed for the church aisle; some walk down it, others will be carried."

20781

294 OF 327

ED

056 238

MICROCOPY RESOLUTION TEST CHART

NATIONAL BUREAU OF STANDARDS-1963-A

4. **Remember:**
   a. Shaded spots on the highway will retain frost and ice when the other portions of pavement are dry.
   b. Bridges will take on frost and retain ice when the rest of the road may be in a safe condition.
5. To prevent skidding when a sudden stop is necessary, apply the brakes lightly and intermittently. This "pumping of the brakes" will reduce momentum without losing traction and without locking the brakes.
6. To start a car on ice, release the clutch slowly, since the tires will have a better chance to grip if the wheels are turning slowly. Starting in second gear will also help.
7. When driving in a snow storm or fog, use the lower headlight beam. The high beam reflects the snow or fog, while the lower beam reduces the amount of reflection. Fog lights, incidentally, are a good investment.
8. Double the distance at which you normally follow behind another vehicle. This is necessary because of the increased distance needed to stop on slippery pavements.

Left of Center On Roadway With Obstruction

When obstruction exists, making it necessary to drive to left of center of highway, right-of-way shall be yielded to vehicles traveling in proper direction on unobstructed portion.

EXPRESSWAY/FREEWAY DRIVING

A new era of driving lies ahead. Superbly-engineered arteries, arrow-straight, like concrete ribbons, allow the traveler, weary from bucking bumper-to-bumper traffic on congested Main Street, to breeze with amazing time saving across the countryside. Expressway/freeway driving is different from the stop-start routine the motorist finds on the normal humdrum roadway. Expressways force the motorist to adjust to a higher speed of travel. Here are some pointers on expressway driving:

How to Get On An Expressway (See diagram)

(1) Slow down and look before turning into an expressway approach.

(2) If you make a mistake, you must proceed with traffic until you reach the next intersection. Leave the expressway and re-enter by the proper approach.

(3) Wait for a let-up in the traffic stream. Expressway drivers are traveling faster than ordinary city drivers.

20782

294

Provides that a concentration of .15 per cent by weight of alcohol in a person's blood is presumptive evidence of such person's intoxication. Provides that a lesser concentration does not constitute such a presumption, but may be considered along with other evidence in determining the person's guilt or innocence.

- Requires that test results be made immediately available to the person or his attorney, if requested. Permits the person to choose another qualified person to administer tests in addition to those directed by a police officer. And provides that failure to obtain additional tests does not preclude the admission of evidence relating to the police department's test.

- Requires driver's licenses to be suspended for a minimum of 30 days for driving while intoxicated (also for traffic homicide by vehicle, perjury, false affidavits, all felonies relating to or involving motor vehicles, and also willfully fleeing a police officer). Also requires that persons convicted of driving while intoxicated receive the prescribed fine and jail sentence (of present law), in addition to the required driver's license suspension.

Special Note: The term "alcohol" has replaced "intoxicating liquor" in the Ohio Code provisions covering drunken driving (Sec. 4511.19). Also, it is now against the laws of the state for any person to consume any beer or intoxicating liquor in a motor vehicle.

SPECIAL DRIVING PROBLEMS

Night Driving

1. The most important precaution to observe for safe night driving is to drive at a cautious, reasonable speed, so as to be able to stop within the distance illuminated by your headlights, should any unexpected hazard appear out of the darkness.
2. Turn on driving lights immediately at sunset, or earlier if twilight visibility is poor.
3. Dim headlights for every approaching vehicle, and when closely following any vehicle. Use the upper beam only for driving in open country with a clear roadway ahead.
4. Watch for pedestrians who may take chances walking along roads or crossing streets because they do not realize that motorists just can't see them.
5. Keep windows clean. The haze and glare caused by lights shining on dirty glass reduce visibility at night.
6. Do not continue driving when sleepy—pull off the road and rest. Fatigue, which slows down perceptions and reaction time, is a significant factor in nighttime accidents.

Winter Driving

1. The first adjustment a driver must make to winter driving is to reduce speed. No matter what road or weather conditions are encountered, a slower speed is the first consideration for safe handling of any vehicle.
2. Be sure that your car is in excellent operating condition. Lights, brakes, windshield wipers, defroster fan, radiator and other parts should be in perfect order, particularly for winter. Use tire chains for severe snow and ice conditions.
3. Open the ventilator or a window just a little. This helps to keep the windshield clear of a fog and guards against possible carbon monoxide leakage.

20783

STOP STREETS AND AUTOMATIC SIGNALS

You must stop before entering or crossing a highway from a private road, driveway, alley or building.

You must yield the right of way to all traffic on said highway.

When you are confronted with a 'STOP' sign or when approaching a highway from an area requiring a stop at such highway—you must come to a full stop even though no traffic is approaching and must yield the right-of-way to all vehicles not obliged to stop.

Know and obey these traffic light signals, arrows:

1. **Green alone**—move through intersection.
2. **Yellow appearing with green**—all traffic stop, except that traffic that has entered the section.
3. **Red alone**—stop.
4. **Green arrow alone**—traffic may move in direction arrow indicates. If arrow indicates a turn, right-of-way must be yielded to pedestrians.
5. **Green arrow appearing with red**—through traffic is prohibited, turn in direction indicated with caution.
6. **Signs may indicate a right turn on red**—turn may be made with caution after stopping if sign so indicates.
7. **A flashing red traffic signal is the same as a stop sign.** You must come to a full stop and only enter the intersection by yielding the right-of-way to all vehicles not required to stop at the intersection.
8. **A flashing yellow traffic signal means caution.** You must slow down and proceed through the intersection with caution.

IMPLIED CONSENT
ALCOHOL CONCENTRATION IN INTOXICATION CASES
PENALTIES

Here are the important provisions:

- Permits such persons to refuse to take such tests, but requires the Registrar, in such cases, to revoke the person's license or driving privileges for 6 months.

- Establishes procedures for advising such persons of the consequences of refusal to take the test, for revoking the license, for hearing, for review, and for notifying the Registrar of other states of cases involving persons from such states.

- Provides that a person who is dead, unconscious, or otherwise incapable of refusing such a test, is deemed not to have withdrawn consent therefor. Also provides procedures for administering such tests to such persons.

- Requires the State Director of Health to determine and approve methods for chemically analyzing bodily substances, in order to determine blood alcohol content. Also authorizes him to determine necessary qualifications of persons to conduct such analyses. And requires him to issue revokable permits to such persons authorizing them to conduct tests. Limits withdrawals of blood for testing to registered nurses or physicians. Permits breath or urine samples to be taken by other persons.

- Authorizes courts to admit evidence on concentration of alcohol, if taken within two hours of violation.

20784

SCHOOL BUS

When meeting or overtaking from either direction, a school bus which has stopped for the purpose of discharging or receiving any school child, **you must stop your vehicle at least 10 feet from the school bus and not proceed until such school bus resumes motion, or until signalled by the driver to proceed.**

When traveling on any highway, which has been divided into two roadways by a physical barrier or clearly indicated dividing section—so constructed to impede vehicular traffic—it shall be necessary to stop, as indicated above, but only when traveling the same direction as the school bus.

PUBLIC SAFETY AND EMERGENCY VEHICLES

On the approach of a public safety vehicle, responding to call, meaning ambulances, vehicles used by public law enforcement officers, and any vehicle used by fire departments—the driver of a motor vehicle is required to pull to the curb and remain stationary until the public safety vehicle has passed.

The driver of any vehicle other than an emergency or public safety vehicles on official business, shall not follow any emergency vehicle or public safety vehicle traveling in response to an alarm closer than 500 feet, or drive into or park such vehicle within the block where the fire apparatus has stopped in answer to a fire alarm, unless directed to do so by a police officer or a fireman.

No streetcar, trackless trolley or vehicle shall, without the consent of the fire department official in command, be driven over any unprotected hose of a fire department, when said hose is laid down on any street, private driveway or streetcar track to be used at any fire or alarm of fire.

Flashing lights are prohibited on motor vehicles, except as a means for indicating turns, or in the presence of a vehicular traffic hazard requiring unusual care in approaching, overtaking or passing. This prohibition does not apply to the use of flashing, oscillating or rotating amber lights on emergency vehicles, road service vehicles servicing or towing a disabled vehicle, traffic line stripers, snow plows, rural mail delivery vehicles, official survey vehicles and funeral escort vehicles.

Except a person operating public safety vehicles, school buses, or vehicles authorized to display slow moving vehicle emblems, no person shall operate or move upon any public street or highway any vehicle or equipment which has a flashing, oscillating, rotating red or combination red or white light.

SLOW MOVING VEHICLES

All farm machinery and other machinery which is designated for operation at a speed of 25 MPH or less shall be operated at a speed not exceeding 25 MPH, and shall display a triangular slow moving vehicle emblem (SMV). Use of the (SMV) emblem upon any other type vehicle is prohibited when such vehicle is operated at a speed of 26 MPH or more. Use of the emblem on stationary objects on the highway is also prohibited.

20785

When making right and left turns, make certain that your directional signals are operating effectively. If necessary, use hand signals as indicated. And don't forget to yield the right-of-way to traffic approaching from the opposite direction.

HAND SIGNALS

Give all signals well in advance. The following hand and arm signals control the operations of a motor vehicle.

1. Left turn—left hand and arm straight out.
2. Slowing or stopping—left hand and arm down.
3. Right turn—left hand and forearm straight up.

It is not necessary to use the hand signals if mechanical directional signals are used.

PROCEDURE FOR MAKING RIGHT & LEFT TURNS

The correct procedure in making:

1. Right turn—Give appropriate signal and stay as near to the right side of the road or curb as possible.
2. Left turn—Give appropriate signal and approach as near to the center line on your left side of the roadway as possible and leave the intersection to the right of the center of the roadway being entered.

The correct procedure for making a left turn from a roadway restricted to one-way traffic is—Give appropriate signal and approach the intersection in the extreme left hand lane entering as nearly as practicable into the left hand lane of the roadway being entered available for traffic in that direction.

RAILROAD CROSSINGS

It is unlawful to drive across a grade crossing:

1. When a crossing gate is lowered.
2. When an electrical or mechanical signal device or a human flagman gives warning of the immediate approach of a train.
3. Flashing yellow lights are sometimes used at railroad crossings, and drivers are urged to use extreme caution when observing these signals.

When a stop sign has been erected at a grade crossing all vehicles shall stop and not proceed until the driver has made certain that no train is approaching.

Note: Use caution though signals have stopped flashing—in the event another train may be approaching.

20787

No vehicle shall be driven on the highway unless it is so constructed or loaded as to prevent any of its load from dropping, sifting, leaking or otherwise escaping.

Any commercial car, trailer, or semi-trailer, with a gross weight exceeding three tons, including load, must be equipped with suitable metal protectors or substantial flexible flaps on the rearmost wheels to prevent, as far as practicable, the throwing of dirt, water or other materials on the windshield of following vehicles.

The regulations governing towing connections for trailers are: When one vehicle is towing another the drawbar or other connection shall be of sufficient strength to pull all weight towed. In addition to such drawbar or other connections, each trailer or semi-trailer not connected to a commercial tractor by means of a fifth wheel shall be coupled with stay chains or cables to the vehicle drawing it. These chains or cables shall be of sufficient size and strength to prevent parting from the drawing vehicle should the drawbar or other connection break or become disengaged. Every trailer or semi-trailer shall be so coupled that the trailer will follow substantially in the path of the vehicle drawing it without whipping or swerving from side to side. When one vehicle is towing another and the connection consists only of a chain, rope or cable, a white flag or cloth not less than 12 inches square shall be displayed upon such connection.

Any vehicle transporting explosives upon a highway must be marked or placarded on each side and the rear with the word 'explosives' in letters not less than eight inches high, or there must be displayed on the rear of such vehicle, a red flag not less than 24 inches square marked with the word 'danger' in white letters six inches high.

Every such vehicle shall be equipped with not less than two fire extinguishers, filled and ready for immediate use and placed at convenient points on the vehicle.

You must obtain a permit from the Department of Highways if you wish to haul a load on the highway that is larger or heavier than the law allows:

INFORMATION ON LIMITATIONS ON MOTOR VEHICLE DIMENSIONS AND WEIGHTS

Width (except municipal bus or traction engine)	8'0"
Width of municipal bus	8'8"
Width of traction engine	11'0"
Height of all motor vehicles	13'6"
Length of single vehicle (except municipal bus)	40'0"
Length of passenger bus type	40'0"
Length of municipal bus	48'0"
Length of commercial-tractor & semi-trailer	55'0"
Length of any other combination	65'0"

Maximum weight (in pounds)

1. On one axle	19,000
2. Total on two successive axles spaced four feet or less, center to center	24,000
3. Total on two successive axles (tandem) spaced more than four feet apart and less than eight feet, center to center	32,000
4. Total on two successive axles spaced eight feet or more, center to center	38,000
5. Total weight of vehicle and load 38,000 pounds plus an additional 900 pounds for each foot of spacing between the front axle and the rearmost axle of the vehicle.	
6. Three axle group, no more than nine feet	48,000
7. Maximum gross load for any combination of vehicles	78,000
8. Maximum wheel load shall not exceed 650 pounds per inch width of tire.

2054

report with the Registrar of Motor Vehicles. Official forms may be obtained from any Government subdivision, Police Department, State Highway Patrol Post, or Deputy Registrar.

FINANCIAL RESPONSIBILITY

Insurance requirements: $12,500 for bodily injury or death of one person in any one accident; $25,000 for bodily injury or death of two or more persons in any one accident; from $7,500 for property damage, and the amount of $30,000 to be deposited with the state treasurer as evidence of financial responsibility.

TRUCK REGULATIONS

The law requires enough space between a truck or a vehicle drawing another vehicle to permit an overtaking vehicle to enter and occupy without danger.

The law requires that operators of motor vehicles carrying passengers for hire, or of any school bus or of any vehicle carrying explosives or inflammable liquids before driving across any railroad grade crossing to:

Stop and listen through an open door or window and look in both directions. He shall cross in such a gear that will not require changing and shall not shift gears while crossing the tracks.

The Director of Highway Safety has the authority to prescribe clearance markers, reflectors and stop lights on buses, trucks, and trailers not operating under the Public Utilities Commission of Ohio.

The law requires a light at night or a flag in the daytime on the load overhang on the rear of a vehicle when the load extends four feet or more beyond the bed of such vehicle.

The following safety equipment shall be carried in all trucks:

1. At least 3 flares, or 3 red reflectors, or 3 red electric lanterns.
2. At least 3 red burning fusees, unless red reflectors or red electric lanterns are carried.
3. At least 2 red cloth flags not less than 12" square with standards to support them.

You, as a truck driver, must take the following steps in case of a breakdown on the highway.

1. Place a lighted fusee or red reflector on the traffic side of the vehicle unless the red electric lanterns are used.
2. Promptly place three lighted flares or red reflectors or three red electric lanterns as follows:
   One at a distance of forty paces to 100 feet to front and one of equal distance to the rear and each in the center of that lane and one on the traffic side of the vehicle. Red Flares shall be used when lights are not required. One shall be placed forty paces or 100 feet to the front and one equal distance to the rear and both in the center of that traffic lane. If disabled, near a curve, crest of a hill or near an obstruction to view, the flags or flares shall be placed to give ample warning, but never less than forty paces or a hundred feet or over one hundred and twenty paces or three hundred feet from the vehicle.

When driving a motor vehicle and hand signals are not visible both to the front and rear, mechanical turn signals must be installed.

Mechanical turn signals must be installed on a vehicle when the distance from the center of the steering post to the left edge of the vehicle exceeds 24 inches and/or when the distance from the center of the steering post to the rear of the vehicle exceeds 14 feet.

UNIT V

BUS MAINTENANCE

71 20790

UNIT V

I. TOPIC

Bus Maintenance

II. ORIENTATION

Each bus, before it is put into operation for a day's work, must have an inspection by its driver. Such an inspection will help insure the safety of both the pupils and the driver. This practice will also decrease the maintenance costs of the pupil transportation program. The daily inspection should become a matter of routine and the few minutes invested may pay rich dividends in the saving of lives and property.

Regardless of the engineering skill or workmanship incorporated in a school bus, it cannot continue to deliver maximum safety, economy, and dependability unless it is properly maintained. Although the repair of school buses is wisely left to a skilled mechanic, the individual driver can do much to aid the mechanic in locating any trouble and often prolong the life of the vehicle by daily inspections.

Every driver should have a basic knowledge of the school bus systems in order for him to know generally how these will affect the bus's operation. There will be times when this knowledge will be useful to the driver in diagnosing trouble while he is on the route. Proper diagnosis of mechanical trouble will increase the efficiency and economy of the operation.

III. PRESENTATION OF MATERIAL

A. Use of Senses

1. Listening for trouble

   a. Sharp knock when picking up speed
   b. Light knock when engine is running at idle speed
   c. Dull regular knock
   d. Clicking or tapping noises
   e. Continuous or intermittent squeal or squeak
   f. Loud exhaust noise
   g. Engine backfiring, missing, popping, spitting, or overheating
   h. Steaming and hissing

Figure 7

20791

2. Feeling for trouble

   a. Excessive vibration

      (1) Engine compartment
      (2) Steering Wheel
      (3) Drive line

   b. Low speed or high speed shimmy
   c. Hard Steering and steering wander

3. Looking for trouble

   a. Sudden drop in oil pressure
   b. Low oil pressure
   c. No oil pressure

NOTE: If any of the above exist, the vehicle shall not be driven until corrected.

Figure 8

   d. Excessive oil consumption
   e. Smoke coming from under dash
   f. Smoke coming from under hood
   g. Scuffed tires or spotty wear

4. Smelling trouble

   a. Odor of gasoling
   b. Odor of burning rubber
   c. Odor of burning oil
   d. Odor of burning rags
   e. Exhaust fumes

5. Any other unusual conditions should be reported immediately to the proper authority.

Figure 9

B. Driver's Daily Maintenance and Inspection Responsibilities

1. Pre-starting inspection

   a. Take a good overall look at the bus

      (1) Oil, gasoline, or water leaks
      (2) Vandalism

20792

b. Open hood - Make sure that safety latch, rod, or hinge is in holding position.

Figure 10
Check Oil Before Starting Engine

(1) Check oil level.
(2) This is the most logical time, as all the oil has drained to the crank case and an accurate reading can be made.
(3) Keep oil above "add oil" line.
(4) Be certain the oil level is not overly full as this may indicate a foreign substance in the oil.

c. Remove the radiator cap and check liquid level. It should be above core level.
d. Check fan belt for proper tension, cracks, and frayed edges.

(1) Most fan belts will operate efficiently if not more than "½ give" is maintained.
(2) A run-down battery in most cases is traced to a loose fan belt and/or a driver's failure to observe his instrument panel occasionally.

e. Look over engine for any loose wires and any excess oil.
f. Close the hood.
g. Wipe windshield turn signals, and warning lights clean.

NOTE: Windshield must be clean before turning on wipers.

20793

h. Start the engine, using proper engine starting procedures (Unit 6, Section B). In allowing the engine to warm up, accelerator should be set for a fast idle. Do not race the engine, as stiff oil will not lubricate fast enough; this can cause bearing damage.

2. First outside-inside inspection

   a. Turn on left directional light, marker lights, and headlights. (high beam)
   b. Front inside of bus, check operating condition of dash-mounted turn indicator signal, high beam indicator, and instrument panel light.
   c. From outside of bus, check left directional signal, marker lights, and headlights. Check for intensity of light, condition of lens, and dark spots on sealed beam unit.

3. Second outside-inside inspection

   a. Turn on right directional lights, warning lights, headlights (low beam), and passenger compartment lights.
   b. From inside of bus, check operating conditions of switches and dash mounted indicators.
   c. From outside of bus, check right directional signal, flasher lights, tail lights, and headlights (low beam). Check for intensity of light, condition of lens, and dark spots on sealed beam units.
   d. Wipe tail lights, stop lights, and headlights clean.
   e. Tires - Check for inflation (use hammer or bar) and general condition.
   f. Wheel bolts - Check visually for tightness, and rust dust around edge of bolt or nut. This is a good indication of a loose wheel bolt.
   g. Emergency door - Check the opening and closing and see that the emergency buzzer is operating.
   h. Windows and mirrors - Check for cleanliness, cracks, or breaks. Good visibility should always be maintained by clean windows and mirrors.
   i. View underneath of bus

      (1) Oil or grease leaks
      (2) Exhaust system
      (3) Springs and hangers
      (4) Body clamps

   j. Body - Check general condition noting any scratches or dents as well as the legibility of bus markings. Many times these markings are coated with so much road dust that they cannot be read nor can it even be distinguished that the vehicle is a yellow school bus.

20794

4. Interior equipment inspection

a. Emergency equipment

(1) Held securely in place
(2) Contents of first aid kit
(3) Contents of fire extinguisher - Note the position of the pressure guage indicator. The needle should always be in full charge area.
(4) Flags, fuses, and reflectors
(5) Wrecking bar

b. Check the horn loudness and operating condition of horn button.
c. Windshield and wipers

(1) Cleanliness of windshield inside
(2) Condition of wiper blades and their operation
(3) Wiper motor and linkage operation

d. Dashboard gauges

(1) Check operating condition and visibility of all gauges.
(2) Attention should be given to these gauges for their proper function at all times when engine is in operation.

e. Check four-way warning hazard switch (when applicable).
f. Brakes - Check

(1) The holding power of the parking brake
(2) The holding power of the parking and/or emergency air brake (when applicable)
(3) For full pedal on foot brake and the position the pedal holds under continued pressure (hydro-vac or hydraulic systems)
(4) Air brakes - depress foot pedal and listen for air leaks.
(5) Brake lights working. This can be checked by having the rear of the bus near a building or by noting the movement of the ammeter hand.
(6) Brake operation before leaving parking lot.

g. Drain water from air storage tank daily

(1) Manual - Use the petcock on the wet-tank drain once daily, preferably at the end of the trip.
(2) Moisture ejectors will operate:
(a) Automatically
(b) Manually - With button on the dash

20795

(3) Local policy

h. Condition of seats and floor
i. Writing on seats and inner skin of body
j. Emergency door operation from inside and wipe rear warning lights
k. Clutch

(1) Chattering or grabbing clutch
(2) The amount of free pedal
(3) A clutch that does not release properly
(4) A slipping clutch

l. Check body instrument panel
m. Steering - When leaving the parking area, check for stiffness and free or loose movement.

5. Bus Cleanliness - Inside and outside

a. The bus must be swept daily. Students should be taught not to throw paper, etc. on the floor.
b. All windows and mirrors should be kept clean. Remember clean windows for clear visibility. In case of an accident, the driver can be cited for vision obstruction.
c. The outside of the bus should be washed as often as needed. Do not allow road dirt to accumulate. Very often just wiping with a dry cloth will remove road dirt if it is not allowed to harden.
d. Seat condition should be checked each time your bus is unloaded. By so doing, any damage can be pin-pointed more effectively.
e. A driver that maintains a clean bus inside and outside will have the respect of the students he transports and they will also take pride in helping to keep a clean bus.

Figure 11

20796

IV. SUMMARY

As one can see after reading the above material, the driver must be alert for malfunctions. Knowing certain noises, feeling certain vibrations, smelling certain odors, and noticing the proper function of all guages may save the driver from a bus breakdown or a serious accident. A school bus inspection is important to the safety of the children being transported by that bus. The inspection need not be made in the same manner as outlined, but a systematic method shall be used so that no part of the bus is missed. Without a safe operating bus and an alert driver, our children will be in danger.

2055

UNIT VI

I. TOPIC

Driving Fundamentals

II. ORIENTATION

School bus drivers have entrusted to them the lives and safety of a human cargo that cannot be measured in terms of dollars and cents. The purpose of this unit on Driving Fundamentals is to teach drivers the basic skills necessary for them to operate buses properly in transporting this valuable cargo safely and efficiently.

The individual driver must not only learn these basic driving skills, but the driver must practice each skill correctly in order to become proficient. Through practice, each correct basic procedure will become a habit to the driver and will contribute to the safe operation of the bus. Experienced drivers who have not had the benefit of organized instruction must be made aware of their faults, and each must make a concerted effort to correct any poor driving practices.

In past years, accidents involving Ohio school buses were caused by the school bus driver in over fifty per cent of the cases. This can be traced in a large part to driver preoccupation and the absence of organized instruction for the driver.

The instructions which follow have been developed to assist the driver in correctly performing the task of driving a school bus. Each section in this unit is based on sound driving practices and procedures. If properly learned and adhered to, these proceudres will result in improving the performance of the bus driver.

III. PRESENTATION

A. **Driver Position** - To be a good bus driver each driver must position himself for comfort, for good vision, and to be within reach of all driver compartment controls.

1. Adjust driver's seat.
2. Adjust seat belt if available.
3. Adjust all mirrors for most advantageous use.

    a. Inside mirror
    b. Outside mirrors should be adjusted so that the driver can see the rear wheel-wells and bumper.

20799

4. The driver should be acquainted with the entire instrument panel and know where each gauge, dial, and switch is located.

B. **Starting the Engine** - The procedure used in starting a bus engine must become a matter of routine. It must incorporate principles of safety and be performed in keeping with good engine preventive maintenance practices.

1. Set parking brake to keep bus from moving.
2. Depress clutch pedal to disengage engine from transmission.
3. Shift gear lever into neutral position to relieve added strain on starter.

   a. Permit additional gears to remain idle.
   b. Check position by moving lever from side to side.

4. Turn on ignition key to complete electric circuits.
5. Engage starter switch.

   a. With clutch depressed and gear in neutral
   b. Use hand choke if necessary and available. Over choking will cause carburetor flooding.
   c. Use foot accelerator sparingly. Pumping will cause carburetor flooding.
   d. Bus engines will vary widely in their carburetor sensitivity; therefore, do not hesitate to ask the supervisor or bus mechanic for special techniques in starting a particular bus.

6. After engine is running

   a. Release clutch pedal slowly without stalling engine.
   b. Allow transmission gears to start rotation.

7. Warm up engine at fast idle.

   a. Do not race the engine.
   b. Much engine wear comes in the first three minutes after starting.

C. **Shifting Gears** - Gear shifting is a phase of bus driving which requires skill and practice. The driver must learn the best range of speed in changing gears upward and downward. Shifting the gears must be accomplished without loss of road vision. Syncro-mesh transmissions have alleviated most of the gear clashing. Generally, buses are equipped with a four or five speed transmission.

1. Know the gear positions.

   a. Check chart on lever knob or on dash.
   b. Ask mechanic.

20800

2. Depress clutch pedal.
3. Shift gear lever into starting gear.

   a. For average terrain and load this should be second gear.
   b. Load and/or terrain may dictate the use of first gear.
   c. Never start out in a gear higher than second as this places undue load and wear on the engine and clutch.

4. Depress foot brake.
5. Release parking brake lever. If ratchet type, pull brake lever slightly back to release pressure.
6. Release clutch gradually to friction point and hold. At this point you will have the clutch just at the point of friction and the foot brake on and ready to release.
7. Depress accelerator. Hold point of clutch friction and slightly depress accelerator to increase the power to prevent stalling.

CLUTCH ELEMENTS

Figure 12

20801

8. Release Clutch.

   a. Slowly and gradually release the clutch to the remainder of pedal travel and at the same time slowly and gradually increase the acceleration.
   b. Remove foot from clutch pedal completely.
   c. Pick up engine speed before shifting to higher gear.

9. Shift to next higher gear.

   a. Depress clutch pedal and release accelerator.
   b. Shift to next higher gear.
   c. Release clutch smoothly but more quickly than in starting gear and depress accelerator smoothly and quickly.

      (1) To prevent loss of vehicle speed
      (2) Do not race the engine and slip the clutch.

   d. Remove foot from clutch pedal.
   e. Proceed in this gear until proper vehicle speed is reached for shifting to next gear.

10. Repeat #9 procedures until the bus is in cruising gear.
11. Never skip a gear in up or down shifting as this causes undue engine and clutch wear.

Approximate M.P.H. to be reached before upshifting or downshifting. M.P.H. may vary slightly depending on make of engine, transmission, gear ratio, and terrain.

Upshifting	Downshifting
From 1 to 2 Gear 1 - 5 M.P.H.	From 5 to 4 Gear 30 - 35 M.P.H.
2 to 3 " 5 - 12 "	4 to 3 " 25 - 30 "
3 to 4 " 12 - 20 "	3 to 2 " 5 - 10 "
4 to 5 " 25 - 30 "	2 to 1 " Stop "

Table 1

20802

12. Shift up or down as may be necessary to prevent engine lugging or excessive engine R.P.M.
13. In going down a hill, shift into the gear that would be used in going up the hill.

D. **Double Clutching** - Syncro-mesh transmissions have almost alleviated the need of double clutching. Shifting the gears on non syncro-mesh transmissions is done faster and smoother by double clutching. This process coordinates the engine speed and transmission speed for non-clashing of gears. Double clutching aligns the gears for easy up and down shifting. The gears should never be forced by improper timing of the shifting process. Reclutching and speeding up the engine will in most cases prevent excessive clashing. The engine should never be allowed to pull heavily going upgrade, on a turn, or on a curve. Neither should it be permitted to over-race downgrade.

1. Double clutching, up shifting

   a. Depress clutch pedal and release accelerator.
   b. Shift gear lever to neutral position.
   c. Release clutch pedal momentarily to engage clutch.
   d. Depress clutch pedal and shift to next higher gear.
   e. Release clutch and accelerate engine at the same time.

2. Double clutching, down shifting (See Table 1)

   a. Depress clutch pedal and release accelerator.
   b. Shift gear lever to neutral position.
   c. Release clutch pedal momentarily to engage clutch and accelerate engine to more than original speed.
   d. Depress clutch and shift to next lower gear.
   e. Release clutch pedal gradually and accelerate engine to match the speed of vehicle.

3. Related items of double clutching

   a. The double clutching procedure may be slow or fast depending upon the type of bus.
   b. Normally down shifting two gears is sufficient.
   c. Double clutching requires continuous practice.
   d. Syncro-mesh transmissions may be double clutched.

E. **Shifting Automatic Transmission** - Some buses are equipped with automatic transmissions and the driver should understand the operation of such transmissions.

1. Know the shift positions.
2. Depress foot brake.
3. Move selector lever into forward or driver position.

20803

4. Release parking brake.
5. Release foot brake and depress accelerator.
6. As speed of bus increases, the transmission will automatically shift to the next higher gear until reaching cruising gear.
7. Down shift for additional power.

   a. Depress accelerator to the floor firmly. This will cause transmission to down shift one gear.
   b. Move selector lever to next lower position.

F. **Steering and Turning** - The school bus driver, to be classified as an expert driver, must be able to assume the correct steering position and make all the turning maneuvers correctly and smoothly. He must learn the correct procedures necesary to prepare for the turn, make the turn, and re-enter the traffic pattern. The driver who is confronted with an unusual turn or turn-a-round shall do so with extreme caution. The raising of speed limits and the super highway system in Ohio, upon which the school buses may travel, has forced the driver to use added skills and judgment in making turns properly and safely.

1. Steering positions

   a. Grip the steering wheel with both hands.
   b. Left hand at approximately 10 o'clock position
   c. Right hand at approximately 2 o'clock position

Figure 13

   d. Hands on outside of steering wheel and thumbs on top or outside of wheel

2. Focus eyes on road ahead.

   a. Eyes should be constantly on the move to obtain the "big picture".
   b. Ahead, left side, right side, rear view mirrors

20304

3. The push-pull steering method is recommended for school bus drivers. One hand pulls and the other hand pushes.
4. Hand over hand method may catch thumb in clothing, safety chain on the wrist watch, bracelets, etc., which are hazards to steering.

Figure 14

5. Preparing for turns

   a. Check traffic to the front and rear of the bus.
   b. Give proper signal to move vehicle into proper lane.

6. Making right turn

   a. Give proper right hand turn signal.
   b. Reduce speed and down shift to proper gear needed to execute turn.
   c. Position bus in right side of the lane.
   d. Check for clear right of way.

      (1) Traffic signals, signs pedestrians, or vehicles
      (2) Use both outside mirrors.

   e. Execute the turn.

      (1) Make turn smoothly without strain on the engine.
      (2) Never shift gears during a turn.
      (3) Check right mirror while executing turn.
      (4) Enter the right most lane available and check turn signal for cancellation.
      (5) Steer wheels back into position -- do not let steering wheel spin wheeks back into position.

Figure 15

20805

7. Making left turn

   a. Give proper left hand turn signal.
   b. Reduce speed and down shift gear.
   c. Position bus to the left edge of the lane.
   d. Check for clear right of way.

      (1) Traffic signals, signs, pedestrians, or vehicles
      (2) Use both outside mirrors.
      (3) If necessary to stop, keep front wheels straight and brake pedal depressed.

         (a) Prevent drifting and activate stop lights.
         (b) This will prevent being shoved into line of approaching traffic if struck from the rear.

   e. Execute the turn.

      (1) Drive into the intersection, make turn smoothly, and without strain on the engine.
      (2) Check left mirror while executing turn.
      (3) Never shift gears in a turn.
      (4) Enter the highway in the left most lane available and check turn signal for cancellation.

LEFT TURN

Figure 16

   f. After completing the left turn upon multiple lane highways, pick up speed and move into right hand lane as soon as possible.

8. Making a turn-a-round

   a. Give brake signal well in advance of turn-a-round.
   b. Stop bus in proper position on roadway.

      (1) One bus length ahead of road to be backed into

20806

(2) Check traffic front and rear.
(3) Visibility shall be 500 feet in either direction (ORC 4511.37).
(4) Have traffic move around bus if possible.
(5) Back into roadway or driveway using outside mirrors.
(6) Re-enter roadway.

(a) Check traffic.
(b) With caution

TURN AROUND

Figure 17

G. **Stoping and Parking Bus** - Stopping a school bus smoothly and within the limits of safety is another sign of an expert driver. A good driver has his vehicle under control at all times and knows that braking distances increase greatly as the speed and weight of the vehicle increases. With a reaction time of one second the driver must realize that at 20 m.p.h. the average stopping distance is 59 feet, and at 40 m.p.h. the stopping distance is 179 feet or approximately three times greater. The skillful driver also knows that by using correct stopping procedures the maintenance costs on the braking system will be less.

20807

Maximum Safe Stopping Distances for TRUCKS and BUSES In Accordance with ICC Regulations				
Speed Miles Per Hour	Feet Per Second	Vehicle Travels (One Second) Reaction Time	Braking Distance	Total Stopping Distance
20	29	29	30	59
30	44	44	67	111
40	59	59	120	179
50	73	73	188	261
60	88	88	270	358
Speed of vehicle.	No. of feet covered per second by vehicle.	Distance traveled in one second before brake can be applied after seeing danger (in feet).	Distance required to stop after brake is applied with good pavement and fair brakes (in feet).	Total feet covered after seeing danger (in feet). Reaction time plus stopping distance.

Table 2

1. Stopping when in a low gear or 10 m.p.h. and less

   a. Depress clutch pedal and release accelerator.
   b. Apply brakes gradually by increasing pressure.
   c. Reduce brake pressure slightly, but not completely just before coming to a stop to prevent jerking.
   d. Shift gear lever into neutral position.
   e. Release clutch and remove foot from pedal.

2. Stopping when in cruising gear

   a. Release accelerator and depress brake pedal.
   b. When proper m.p.h. is obtained for any gear, down shift to next lower gear. See Table 1.

      (1) Will reduce heat build-up
      (2) Reduce excessive brake wear

20808

C. Meat and Poultry Cookery

Essential learning (Skill and knowledge)	Scope of instruction (Suggested content)	Information (Technical and related)
Roasting		
How to roast meats:	Explanation of roasting principle:	Characteristics of grades and cuts suitable for roasting
The understanding and application of recipes, formulas, and precedures	Beef	
	Pork	
	Veal	
	Lamb and mutton	
	Care and storage before roasting	
	Preparation:	Equipment:
	Fresh meats	Roast pans
	Frozen meats	Meat thermometers
		Oven thermometers
		Other equipment
	Procedure:	Shrinkage:
	Seasoning	Cause
	Roasting temperatures	Effect
	Time	Control
		Cost
	Testing for doneness	Methods of testing
		Methods of serving:
		Gravies
		Jellies
		Garnishes
	Carving	Carving:
		Tools
		Portions
	Care of meat:	Use of drippings, fat, and trimmings
	After roasting	
	During serving period	
	Storage	
		Calculation of costs
How to roast poultry:	Explanation of roasting principles:	Classification of poultry
The understanding and application of recipes, formulas, and procedures	Turkey	Effect of roasting
	Chicken	Nutritive value
	Capon	Characteristics of poultry suitable for roasting:
	Duck	Age
	Goose	Weight
	Preparation for roasting:	Equipment:
	Drawn (viscerated) poultry	Roast pans
	Undrawn (nonviscerated) poultry	Thermometers
	Frozen poultry	
	Procedure:	Shrinkage:
	Seasoning	Cause
	Basting	Effect
	Vegetable garnishes	Control
	Roasting temperatures	Cost
	Time	
	Carving	Carving:
		Tools
		Portion control
		Variation in roasting procedure for ducks and geese

2056

c. Down shifting can be very effective and smooth.

(1) 3rd gear for 5 speed transmission
(2) 2nd gear for 4 speed transmission

3. Parking the bus

a. Shift lever into low gear on level or upgrade.
b. Shift lever into reverse gear on down grade.
c. Turn wheels into curb.
d. Turn off ignition and remove ignition key.
e. Set parking brake (Parking brake may freeze in wet freezing weather.)

H. **Loading and Unloading** - The loading and unloading of pupils presents the driver with additional responsibilities and requires use of good judgment. The driver must learn the proper procedure for controlling traffic, for pupils crossing roadway, for pupils entering the bus, and for pupils seating themselves.

1. Loading

a. Check traffic - oncoming.
b. Check traffic - behind -- using mirrors.
c. Activate flasher lights approximately 300 feet before the stop.

(1) Warn traffic in front and to the rear of the bus in sufficient time.
(2) This will vary depending upon conditions.

d. Bring bus to stop using proper procedure (refer to Section G, Number 1 and 2).
e. Do not stop where visibility to front and rear is less than 500 feet.
f. Put gear shift lever into neutral.
g. Re-check traffic to front and rear of the bus and make certain traffic has come to a stop.
h. Open entrance door and signal pupils it is safe to cross in front of the bus.

(1) Pupils should be taught to cross at least 10 feet or 5 paces to the front of the bus.
(2) Instruct child to cross at distance where he can see the driver.
(3) Safety - cross mirrors are helpful.

i. Systematic loading can be very helpful.

(1) Various systems can be used.
(2) Pupil concentration must be considered.

20809

(3) Two pupils per seat starting from rear.
(4) Three pupils per seat starting from rear.
(5) Do not allow students to stand in step well or forward of the driver stantion.

j. Proceed when all students are seated.

(1) Shift into starting gear.
(2) Close the door.
(3) Check to see that all students are seated. Check traffic and move out slowly and smoothly.

2. Unloading

a. Follow the same procedure as outlined in loading under a., b., c., d., e., f., g., h.
b. Proceed when pupils are in complete safety on their residence side of road.

3. Unloading at school building

a. Stop bus using proper procedure.

(1) Place gear shift lever in low gear.
(2) Turn off ignition.
(3) Set parking brake.

b. Do not activate warning flasher lights.
c. Driver stand and face students.

(1) All students remain seated.
(2) Unload front seat entrance side first, then front seat driver side. Continue alternating to the rear of the bus.
(3) This unloading procedure promotes safety and efficiency.
(4) Develops good habits in case of emergency evacuation.

Figure 18

If In Full Control, Driver Need Not Deactivate Unit

20810

Shall Deactivate Unit Prior To Standing

Figure 19

Shall Deactivate Unit Prior To Turning Sideways

Figure 20

I. **Railroad Crossing** - Through planned safety procedures for crossing railroad tracks, many accidents could be eliminated. Learn these procedures and practice them until they become automatic actions.

Crossing railroad tracks represents one of the greatest hazards insofar as mass casualities and fatalities are concerned. STOP, LOOK, and LISTEN. All school buses loaded or empty must stop for railroad crossings.

1. Prepare to stop.

   a. Request silence.

      (1) This is a must.
      (2) Turn heaters off if necessary to have more silence.

20811

b. Get "Big Picture", check traffic control devices.

2. STOP the bus.

   a. Follow stopping procedures.
   b. Stop in a position that gives a clear view of the tracks in both directions. The front bumper must be clear of the tracks.
   c. Shift into neutral.

3. LOOK and LISTEN.

   a. Open service door and driver's window.
   b. Look and listen through the open window and door.

4. If no indication of approaching train

   a. Shift into starting gear.

      (1) Must be a gear that will take bus across tracks without hesitation.
      (2) Shifting gears on tracks shall not be permitted.

   b. Look and listen a second time, close door, and proceed quickly and smoothly.

5. If there is an approaching train

   a. Hold bus position, may use the parking brake depending on waiting time.
   b. After train passes, follow items under Procedure 4.

6. Multitrack crossings

   a. Make sure no train is approaching on any of the tracks.
   b. After a train passes, wait until other tracks become visible before proceeding. A second train may be approaching from the opposite direction.
   c. Follow items under Procedure 4.

7. Railroad traffic control devices

   a. Flasher lights and bells

      (1) Warning of an approaching train
      (2) If train is stopped or signal is malfunctioning, a vehicle may proceed after driver insures a safe crossing can be made.

   b. Gates

      (1) All traffic must obey these devices.

20812

(2) Vehicles may proceed around the gates only at the direction of a peace officer or an authorized railroad representative.

c. Railroad crossing controlled by a flagman

(1) A school bus must make a safety stop.
(2) Follow directions of the flagman.

J. **Unusual Weather and Road Conditions** - A good driver will adjust his driving to all kinds of weather and road conditions to stay within the limits of safe driving. Bad weather may excuse a delay, but never an accident.

1. Conditions causing slippery roads

a. Rain
b. Freezing rain
c. Snow
d. Wet leaves
e. Spillage of oil, etc ., from trucks
f. Mud

2. Procedures for safe driving on slippery roads

a. Slow down.
b. Use brake fanning action. Sudden braking will cause skidding and loss of steering traction.
c. Allow more distance for driving action.
d. Allow more distance when signaling.

3. Conditions causing poor visibility

a. Rain
b. Snow
c. Clouds
d. Fog - Smoke
e. Inside bus fogging

4. Procedures for safe driving in poor visibility.

a. Slow down.
b. Use windshield wipers and defrosters.
c. Turn on marker lights and head lights.

NOTE: Driving with lighted parking lights is illegal.

d. Sound horn at intersections, curves, and other dangerous places.

20813

5. Road conditions caused by freezing, thawing, and rain

   a. Soft and spongy roads
   b. Chuck holes
   c. Broken road sections
   d. Humps

6. Procedures for safe driving on poor road conditions

   a. Slow down.
   b. Be alert for these conditions during the proper seasons.

7. Procedures when driving off roadway onto soft shoulder

   a. Slow down.

      (1) Brake gently.
      (2) Hold steering wheel firmly and steer along berm.

   b. Drive on shoulder.

      (1) Keep bus moving.
      (2) Look for place to pull onto the roadway.
      (3) Check traffic in front and rear.

   c. Turn onto roadway.

      (1) Hold steering wheel firmly.
      (2) As soon as front of bus is on roadway, return bus to normal position.
      (3) Do not allow bus to cross into next lane of the road.

8. Procedures for controlling skid

   a. Remain calm.
   b. Release accelerator.
   c. Do not put on the brakes.
   d. Turn front wheel in direction of the skid.

      (1) Make smooth turn and not too quickly.
      (2) Do not over steer.
      (3) This turn will bring front end of bus in line with rear end.

   e. Be ready to make the opposite turn as bus begins to re-align with the road.

      (1) This turn will need to be made more quickly.
      (2) Turn only enough to keep bus in line with the road.

20814

K. Types of Roads and Speed Limits

1. Interstate - bus speed limit 55 M.P.H.
2. State Highway and Turnpike - bus speed limit 50 M.P.H.
3. Entering and leaving freeway

   a. Use acceleration lane to pick up speed.
   b. Yield right of way to roadway traffic - stop only if necessary.
   c. Pick an opening in the traffic and move into the flow.
   d. To leave the roadway, activate turn signal and move from right lane into deceleration lane.
   e. Slow down for exit.
   f. Use proper turn signals.

Diagram from Ontario (Canada) Department of Transport

Figure 21

4. Multilane and limited access highways - speed limit 50 M.P.H.

   a. These may or may not have short entrance and exit lanes.
   b. Entering traffic must yield the right of way.
   c. Exiting traffic must slow down for sharp turn off.

20315

5. Other state roads - bus speed 50 M.P.H.

   a. Seldom have entrance and exit lanes.
   b. Entering traffic must stop.

6. County and township roads - bus speed 50 M.P.H.

   a. The roads will run from good hard surfaced to dirt.
   b. Actual speed will be determined by the conditions of the road.

IV. SUMMARY

Before starting a bus, the driver should have complete vision all around him and be comfortably seated. The driver should be well skilled in the driving fundamentals of the bus before he attempts to drive it. It is his job to transport children and he should do his best to contribute to the safe operation of the bus.

Starting the bus, shifting gears, and double-clutching all require skill and practice. The driver should be able to do this efficiently as he watches the road ahead.

Steering and turning the bus are very important to the driver in his daily routine. He must be able to handle the bus properly whether on a deserted road or a road with heavy traffic. Stopping a bus smoothly and within the limits of safety is another sign of an expert driver. Parking procedures should be known well and practiced.

Loading and unloading presents the driver with additional responsibilities and requires the use of good judgment. He is responsible for the safety of the children on his bus and he must comply to the rules of loading and unloading a bus. He is to get the children <u>to</u> school and <u>from</u> school <u>safely.</u>

Bad weather presents the driver with some additional hazards. However, if the driver realizes the problems involved, he can take the necessary precautions to cope with these hazards.

Procedures before crossing a railroad crossing are extremely important. The driver should watch the railroad signals, open the door, look, and listen carefully up and down the tracks to see if a train is approaching. The parents, supervisors, and children of the community depend on the driver, so he must do his best to operate his bus skillfully and safely to maintain their faith in him.

20816

UNIT VII

I. TOPIC

Defensive Driving

II. ORIENTATION

Defensive driving may be defined as being able to drive in such a way as to avoid being involved in traffic accidents, regardless of another driver's actions, or the driving conditions. It is very important that the school bus driver should know, not only the purpose of defensive driving, what defensive driving is, and why defensive driving is needed, but the driver must master all of the driving skills in order to become a good defensive driver

III. PRESENTATION

A. **Purpose of Defensive Driving Is To Reduce Chances of Becoming Involved In An Accident**

B. **What Is Defensive Driving?**

134 143 144
1. Being careful not to commit driving errors
2. Making allowances for the lack of skill on the part of other drivers and self
3. Making allowances for hazardous weather conditions
4. Recognizing an accident producing situation far enough in advance to take preventive action
5. Yielding the right of way when necessary to prevent an accident

C. **Why Defensive Driving Is Needed**

1. To cope with the tremendous increase in the number of vehicles on the highway
2. To protect passengers, pedestrians, and self

D. **Defensive Driving Skills**

1. Major factors that should be known and practiced to keep from being involved in a motor vehicle accident.

   a. Observe and evaluate the big picture

      (1) Vehicles ahead
      (2) Vehicles behind

20818

C. Meat and Poultry Cookery—Continued

Essential learning (Skill and knowledge)	Scope of instruction (Suggested content)	Information (Technical and related)
Roasting—Continued		
How to roast poultry—Continued	Testing for doneness	Methods of testing Methods of serving: Sauce Gravy Garnishes
	Stuffings and dressings: Types Variations in methods of preparation	
	Care of fowl: After roasting During serving period Storage	Related science Calculation of costs
Broiling		
How to broil different kinds of meat: The understanding and application of recipes, formulas, and procedures	Explanation of broiling principle	Purpose and effect of broiling: Beef Veal Lamb Pork
	Preparation: Fresh meat Frozen meat	Equipment Fuels used for broiling Manipulation of broiler
	Procedure: Seasoning Searing Temperature Broiling time: Fresh meat Frozen meat Thickness	Variations: Barbecuing
	Testing for doneness	Methods of testing Methods of serving: Sauces Gravies Butters Garnishes Calculation of costs
How to broil poultry: The understanding and application of recipes, formulas, and procedures	Preparation	Characteristics of poultry suitable for broiling: Weight Age Effect of broiling upon flesh of chicken Manipulation of broiler for proper heat
	Procedure: Seasoning Searing Basting Care while broiling Temperature Timing	
	Testing for doneness	Methods of testing Calculation of costs

2057

(3) Vehicles approaching from opposite direction
(4) Vehicles approaching from an angle
(5) Vehicle passing
(6) Vehicle being passed
(7) Pedestrians
(8) Adverse weather conditions

b. Actions of the other driver which can cause an accident

(1) Vehicle in front slowing down, stopping, or backing
(2) Vehicle behind following too closely
(3) Driver of vehicle approaching driving left of center, cutting across in front, or failing to dim headlights
(4) Vehicle approaching from an angle, pulling or backing across driver's path
(5) Vehicle that is passing, cutting back into the lane of traffic too quickly, or passing on the right
(6) Vehicle that is being passed racing into driver's path, or pulling from curb without looking

c. Defensive action that can be taken to keep from being involved in an accident.

(1) Maintain safe following distance.
(2) Watch for conditions ahead that would cause the driver in front of the bus to stop suddenly.
(3) When a car is following too closely behind

(a) Check mirrors frequently.
(b) Signal well in advance when slowing or stopping.
(c) Make slow gradual stops.
(d) Make authorized stops only.

(4) When a vehicle is approaching from an angle.

(a) Be prepared to stop at alleys, intersections, and driveways.
(b) Look in all directions before entering intersections.
(c) Double check at blind intersections.
(d) Move into intersection on green light after looking to right and left.

(5) When another vehicle is passing

(a) Slow down.
(b) Pull to the right.

(6) Maintain position in proper lane.

20819

(7) When passing another vehicle

(a) If the other vehicle attempts to race, slow down and let it proceed.
(b) Make audible signal before passing.
(c) Check position of other vehicle before passing.
(d) Maintain proper distance between school bus and parked vehicles. See Figure 22.

Figure 22

(e) Do not cut in too quickly after passing another vehicle.

2. Defensive driving is an art which does not permit preoccupation or inattention on the part of the driver.

IV. SUMMARY

Due to a tremendous increase in the number of vehicles and higher speeds, the potential for accidents is greatly increased. Proper application of defensive driving practices can substantially reduce the potential.

20820

UNIT VIII

SAFETY AND EMERGENCY PROCEDURES

20821

UNIT VIII

I. TOPIC

Safety And Emergency Procedures

II. ORIENTATION

The driver is responsible for the safety and well-being of the passengers in his bus as well as for the safe operation of his vehicle. He is in full charge of the bus at all times. His knowledge of proper emergency procedures, emergency evacuation procedures, and accident scene procedures is a must! These areas of responsibility deal directly with the safety and care for his passengers in the event of an accident, as well as other emergency situations which may arise.

The driver must know:

A. What to do

B. How to do

C. When to do

III. PRESENTATION

A. Know the Emergency Equipment on the Bus and How to Use It

1. Fusees — as warning devices

   a. Thirty-minute fusees encased in a metal container
   b. Located in driver's compartment
   c. Lighting of fusees

      (1) Grasp fusee in right hand.
      (2) Twist and lift off cap with left hand.
      (3) Strike fusee across cap.
      (4) Point ignited end away from body.

   d. Placement of warning devices (fusees)

      (1) One fusee is placed at the side of bus on roadway side – safe distance from bus and oncoming traffic.

20322

Figure 23

(2) Place second fusee approximately forty paces of one-hundred feet to rear of bus.

(a) Placement distance should be greater if bus is on a hill or curve.
(b) Not to exceed three-hundred feet

(3) Place third fusee forty paces or one-hundred feet to front of bus again using greater distances if conditions warrant.

2. Red flag and red reflectors as warning devices

a. Three red flags and three red reflectors are located in the driver's compartment.
b. The flags are for day time use.
c. The reflectors may be used both day and night.
d. Follow same directions for placement as was explained for fusees.

3. Use four way hazard flashers with good judgment.
4. Fire extinguisher

a. One two and one-half pound dry-chemical type fire extinguisher (or larger) is located in driver's compartment.
b. Operation of dry chemical fire extinguisher

(1) Remove extinguisher from mounting bracket.
(2) Hold extinguisher in vertical position.
(3) Release safety device.
(4) Squeeze handle to discharge chemicals.
(5) Direct chemical discharge at the base of the flame.

20323

c. A two and one-half pound extinguisher has approximately thirty seconds of use.
d. Recharge fire extinguisher after every use.

(1) Test
(2) Actual fire
(3) Gauge indicates red

5. Wrecking bar

a. Nearly all buses presently in use (since 1961) are equipped with a twenty-four inch wrecking bar (older buses may still carry a small axe.)
b. The wrecking bar is usually located close to the driver's compartment.

(1) Under front passenger seat
(2) On the firewall
(3) By driver's seat

c. Purpose of wrecking bar is to pry open doors, windows, etc., in the event of an accident where damage to vehicle prevents easy exit by normal means.

6. First aid kit

a. The first aid kit should be located in the driver's compartment, be dust-proof, well-labeled, and conform to federal standards. Standards require a 16 unit kit for buses carrying up to forty-two passengers and a 24 unit kit for larger buses.
b. For first aid, see Unit IX - First Aid.

7. Replace any item used from emergency equipment supplies as soon as possible.

B. Emergency Procedures for Mechanical Breakdowns

1. Move bus off roadway if possible to prevent accidents with other vehicles.
2. Turn off ignition switch and remove key.
3. Set the hand brake.
4. Use warning devices as explained in previous section "A" subheading 1., 2., 3.
5. Request assistance from passing motorist to notify school officials of bus location and possible difficulty.

a. Ask at least two different motorists to contact the school.
b. Provide them with proper phone number to call.

6. If no motorists are avialable, sent two reliable male students to nearby home, place of business, etc., to make telephone call to school officials.

20824

7. Keep pupils on the bus in most cases.

NOTE: Exception to above rule -- safety conditions may warrant removal because of possible fires, extremely dangerous section of highway, etc.

C. Accident Procedures

1. Turn off ignition switch, ground disconnect switch, and remove keys.
2. Set the hand brake.
3. Remain calm and reassure students.
4. Be alert for fire or the possibility of fire.

   a. Check for ruptured gas tank and fuel line; can be a potential furnace.
   b. Check for electrical fire.
   c. Look for smoke.
   d. Check for hot tires which may catch fire.

5. Use warning devices. See Section A., 1., 2., 3.
6. Check for injury of pupils.

   a. If pupils are injured, follow first aid procedures.
   b. See Unit IX.

7. Keep all pupils on bus.

NOTE: Exception -- conditions may warrant their removal such as: possibility of fire of if bus is situated in extremely dangerous section or roadway.

8. Account for all pupils.
9. Notify state highway patrol or other legal investigating officer.
10. Notify school administrators of the location of the bus and accident.
11. Protect the scene

    a. Protect the students and the bus from further accidents and injuries.
    b. Protect the scene from traffic and people so that evidence is not destroyed.
    c. Under normal circumstamces, the vehicles involved should not be moved until law officer advises the driver to do so.

12. Do not discuss the facts of the accident with other motorists; but give information only to investigating officer and school officials.

    a. Provide necessary information to the investigating officer.

       (1) List of students' names, ages, and addresses
       (2) Information about the school bus such as insurance, make, model number, owner, etc. (Carry emergency packet on the bus which

20825

includes bus information, emergency telephone numbers, ball point pen, pencil and tablet.)

b. While being investigated; be patient, evaluate questions, and give clear and concise answers.
c. Drivers in an accident are required to give their name, address, driver's license number, and vehicle information. Be ready to give this information to the other driver and also receive and write down the same information from the other driver involved.
d. If witnesses were present, get names, addresses, and license numbers.

13. Cooperate with school administration.

a. Continue the transportation of the students.

(1) By the present bus
(2) By spare bus
(3) By some other means

b. But not until authorized to do so

14. Prepare necessary written reports required by the school district and by law.

a. Accident report which must be forwarded by the driver to the Bureau of Motor Vehicles
b. Local school district reports

(1) Start as soon as possible to prepare accident reports.
(2) Make a record of necessary items at the scene of the accident.

D. **Emergency Evacuation of School Buses** -- In the interest of safety, all bus drivers should conduct an emergency evacuation drill through the front door when they unload at the schools at least once a month with each bus load of children.

1. Front door evacuation of school buses

a. The bus is stopped, parking brake set, and engine turned off.
b. The driver will stand, open the door, face the children, and get their attention.
c. The driver will give the command "Emergency drill, remain seated, front evacuation". If driver is incapacitated the bus helper will assume the responsibility.
d. Advise bus helper to guide passengers to assigned place of safety.
e. A second bus helper will stand outside of the bus by front door to count and assist passengers as they evacuate.
f. Any standees in the aisles then move out in good order, stay in a line, and follow bus helper to place of safety.

020826

g. Standing between the first occupied seats, the driver will then turn and face the front of the bus.

   (1) Starting with the right-hand seat, the driver taps the shoulder of the person nearest the aisle to indicate that those occupants shall move out.
   (2) The driver will hold his hand before the occupants of the left-hand seat in a restraining gesture.

h. When the pupils of the dismissed right-hand seat have moved forward far enough to clear the aisle, the driver dismisses the occupants of the left-hand seat.
i. The evacuation continues as described, right-hand and left-hand seats alternately, until the bus is empty.
j. When the last seat is empty, the driver walks to the front of the bus, checking to see that all are out.

   (1) This check must be made fron the extreme rear of the bus forward.
   (2) Be certain to check between and under seats.

k. As the driver leaves the bus, he removes the fire extinguisher, first aid kit, and can of fusees and takes them with him or assigns this duty to a reliable student.
l. The driver shall conduct a count of the pupils to assure that all are accounted for.

2. Rear emergency door evacuation – used when front door is <u>not</u> accessible.

   a. Appoint two responsible pupils on each load who are among the first to board the bus to sit by the rear door, one each side of the aisle.
   b. A third person may be appointed to lead the students to a place of safety designated by the driver, or of his choosing if none is designated by the driver.
   c. The appointee in the left-hand seat shall have two responsibilities:

      (1) To see that nobody touches the door latch
      (2) To open the door on command of the driver or, if the driver is unable to give such a command, to open it when he sees that a rear evacuation is necessary.

   d. The bus driver gives command "Emergency drill - remain seated - rear evacuation".
   e. Both helpers, the one who opened the door, and the other from the right-hand seat, then jump to the ground and aid the others in the evacuation, first emptying the aisle, then, beginning with the rear seats, alternating right and left until the bus is empty.

20827

f. The driver keeps the children under control, and makes sure that the bus is empty as he follows the last pupil out of the rear door, taking the fire extinguisher, first aid kit, and can of fusees with him.

g. The same instruction concerning the grouping of children and driver's responsibility as are given for a front door evacuation are effective for rear door evacuation.

E. Safety Awareness

1. Control children to prevent falls, fights, etc.
2. Control the physical aspects of the inside of the bus such as safe floor (no ice, banana peel, etc.) safe windows, etc.
3. Be prepared for icy weather with wiping rags, ice scraper, etc.
4. Have windshield wiper and defroster in working order. Use ventilation to reduce moisture inside.
5. Have lights, both inside and outside in working order.
6. Use braking light to indicate to those following the bus that the driver is preparing to stop or reduce speed.
7. Use flasher lights in such a manner that oncoming traffic will have ample time to stop.
8. The driver should use the seat belt at all times when operating the vehicle.

IV. SUMMARY

A. Accidents are going to happen.

B. Accidents do not always occur to the "other driver".

C. When accidents occur, it is too late to begin teaching emergency procedures.

D. Have a plan of action necessary for emergencies.

E. Instruct the pupils, through drills and talks, of their responsibilities and proper conduct for emergency situations.

F. The driver must not panic or show nervousness during an emergency situation.

20928

C. Meat and Poultry Cookery—Continued

Essential learning (Skill and knowledge)	Scope of instruction (Suggested content)	Information (Technical and related)
Braising		
How to braise meat:	Explanation of braising principle	Cuts and grades of meat used for braising
The understanding and application of recipes, formulas, and procedures	Preparation:	Equipment
	Marinating	Purpose of:
	Larding	Marinating
		Larding
	Procedure:

UNIT IX

FIRST AID

116/117 20829

UNIT IX

I. TOPIC

First Aid

II. ORIENTATION

The first objective of first aid is to save life. Therefore, it becomes necessary to know and understand the principles of first aid. First aid is the immediate and temporary care given to the victim of an accident or sudden illness until the services of a physician can be obtained.

First aid teaches more than how to apply a dressing or a splint. It teaches competence, which should be displayed by the person administering first aid to the injured. A victim will respond much more readily to treatment if he recognizes that a competent person is administering that treatment.

Common sense and a few simple rules are the keys to effective first aid. It is important to know what not to do, as well as to know what to do. In case of an emergency, making mistakes could be disastrous to the injured person.

First aid training is a necessity for everyone. It can be beneficial in the home and in the community, not only to give assistance in case of emergency, but to promote accident prevention and safety consciousness.

The so-called "Good Samaritan Law" is quoted from Ohio Revised Code, Section 2305.23, Liability for emergency care:

> "No person shall be liable in civil damages for administering emergency care or treatment at the scene of an emergency outside of a hospital, doctor's office, or other place having proper medical equipment, for acts performed at the scene of such emergency, unless such acts constitute willful or wanton misconduct.
>
> Nothing in this section applies to the administering of such care or treatment where the same is rendered for remuneration or with the expectation of remuneration. (130 v S14. Eff. 9-16-63.)"

III. PRESENTATION

A. **General Directions** - In case of a serious injury, the first concern of the person administering first aid is to save life. This may be accomplished by administering immediate and temporary care in the following manner.

1. Prevent heavy loss of blood.

   a. Heavy bleeding comes from severing one or more large blood vessels which can kill the victim in 3 to 5 minutes.

   b. Heavy bleeding may be controlled by using the following methods:

      (1) Place a pad, clean handkerchief, clean cloth, etc., over the wound and press firmly with the hand or both hands. If a pad or bandage isn't available, close the wound with the hand or fingers. See Figure 24.
      (2) Apply pressure directly over the wound.
      (3) Hold the pad firmly in place with a strong bandage, necktie, cloth strip, etc.
      (4) Raise the bleeding part higher than the rest of the body, unless bones are broken.
      (5) Keep the victim lying down.
      (6) Call a physician.

Figure 24

   c. Use of body pressure points to control severe bleeding.

      (1) Severe bleeding may be partially controlled by using the fingers or heel of the hand to press the supplying blood vessels against the underlying bone.
      (2) There are six points on each side of the body where pressure against the supplying vessel is of practical use. These Points are indicated by the black spots on the diagram. Pressure applied at any of these points will slow bleeding beyond this point. See Figure 25.

Figure 25

20831

d. A tourniquet should never be used to control bleeding, except for an amputated, mangled, or crushed arm or leg.

(1) To apply a tourniquet for an amputated arm or leg, use only a strong wide piece of material. Wrap tourniquet around the upper part of the limb, above the wound. Tie a half-knot; place a stick on the half-knot and tie a full knot above the stick; twist the stick just enough to stop the bleeding. See Figure 26.

(2) The time that a tourniquet is applied should be marked or written in a very prominent place, on or near the victim (write time on forehead).

Figure 26

2. Maintain Breathing - There is a need for artificial respiration when breathing movements stop, or lips, tongue, and fingernails become blue. No harm can result from the use of mouth to mouth respiration, and delay may cost a victim his life. There are a number of methods of artificial respiration used to induce breathing and they are administered in the following manner:

a. Mouth to mouth breathing is one of the newest and most effective methods of artificial respiration because of the direct force of air into the victim's lungs. It can be administered to a victim without the need for special equipment, and in almost any position or location. Rescuers can maintain mouth to mouth breathing for hours without fatigue. They can also see, feel, and hear the effect of each lung inflation as well as being able to control the amount, rate, and pressure of air being administered. The following procedure is used to administer mouth to mouth breathing:

(1) Place victim half-way between a face-up and a side position.
(2) Lift victim's neck with one hand and tilt his head back by holding the top of his head with your other hand.
(3) Pull the victim's chin up with the hand that was lifting the neck so that the tongue does not fall back to block the air passage. Clear air passage of foreign objects.
(4) Take a deep breath and place your mouth over the victim's nose or mouth, making a leak-proof seal. Close nose by pinching.

FOR CHILDREN, COVER MOUTH AND NOSE. See Figures 27, 28, and 29.

20832

Figure 27

Figure 28

Figure 29

(5) Blow your breath into the victim's mouth or nose until you see the chest rise. The air you blow into the victim's lungs has enough oxygen (3/4 of oxygen remains) to save his life.
(6) Remove your mouth and let the victim exhale while you take another breath.
(7) As soon as you hear the victim breathe out, replace your mouth over his mouth and repeat procedure.

REPEAT 15 TIMES PER MINUTE.

b. FOR CHILDREN: When possible, place your hand over the child's stomach. Use a moderate pressure to keep the stomach from becoming inflated. CAUTION: Very light pressure should be used when using mouth-to-mouth respiration on small children.

c. Manual Method of Artificial Respiration should be used if for any reason the mouth-to-mouth method cannot be used.

(1) Place victim in a face-up position.
(2) Place something under victim's shoulders to raise them and allow the head to drop backward.
(3) Kneel above victim's head, facing the victim.
(4) Grasp victim's arms at the wrists, crossing and pressing victim's wrists against the lower chest.
(5) Immediately pull upward, outward, and backward, as far as possible.

REPEAT 15 TIMES PER MINUTE.

(6) If a second rescuer is present, he should hold the victim's head, so that it tilts backward and the jaw juts forward.

Figure 30

20833

3. Recognizing and preventing shock -- Shock usually accompanies severe injury or emotional upset. It may also follow pain, disturbance of circulation from bleeding, stroke, heart attack, heat exhaustion, extensive burns, etc.

   a. A state of shock may be recognized by some of the following symptoms:

      (1) Cold and clammy skin
      (2) Pale face
      (3) Nausea or vomiting
      (4) Shallow breathing

   b. Life may be saved by prevention of shock.

      (1) Correct cause of shock, is possible.
      (2) Keep victim lying down.
      (3) Keep breathing airways open.
      (4) Elevate victim's legs if there are no broken bones.
      (5) Keep head lower than trunk of the body, if possible.
      (6) Keep victim warm if weather is cold or damp.
      (7) Give fluids (water, tea, coffee) if victim is conscious and can swallow (no alcoholic beverages).

B. In case of involvement in a serious accident, the first concern of the person administering first aid is to save life. After this phase is past, it then becomes necessary to attend to other injuries of persons involved. These injuries may be of a serious nature, but not likely to cause immediate death. It is, therefore, necessary to be able to recognize and administer first aid to the following:

   1. Recognizing and Treating Bone Injuries

      a. In case of injury to spine or neck:

         (1) Do not move victim or allow him to be moved until a proper stretcher is available.
         (2) A physician should be called immediately and should be present to supervise moving the victim, if possible.
         (3) Keep the victim warm and quiet.
         (4) Watch breathing and be prepared to start mouth to mouth breathing - but do not move the head.

20834

b. Fractures

(1) First aid to broken bones should do no more than prevent further injury. There are two types of fractures:

(a) Simple or Closed - The bone is broken but the skin has not been punctured.
(b) Compound or Open - The skin is broken as well as the bone.

(2) Do not move the injured person until the suspected fracture site has been splinted, unless the victim is in imminent danger.
(3) Place the limb in as natural a position as possible without causing discomfort to the victim.
(4) Apply splints. Splints must be long enough to extend well beyond the joints above and below the fracture. Any firm material can be used: board pole, metal rod, or even a thick folded newspaper.
(5) Use clothing or other soft material to pad splints to prevent skin injury. Fasten splints with bandage or cloth at a minimum of 3 sites:

(a) Below joint below break
(b) Above joint above break
(c) At level of break

(6) Broken bones in the hand or foot can be held steady with a pillow or blanket bound around it.

Simple or Closed Fracture

Compound or Open Fracture

Figure 31

2. Head Injuries

a. Consider anyone found unconscious to have a possible head injury, and take the following precautions:

(1) Call a physician immediately.
(2) Keep the victim lying down, preferably on his side so that the air passage will not become blocked and to allow for drainage of blood, vomitus or other fluids.
(3) Keep victim warm, if weather is cold or damp.

Figure 32

Figure 3

20835

(4) Control bleeding from a head wound by applying a pressure dressing. Caution should be used in regard to using pressure over a possible skull fracture.
(5) Do not move the head or any part of the body if there is bleeding from the nose, mouth, or ears.

b. Unconsciousness could be the result of a head injury, and should be treated as described before. The same precautionary measures should be used. Caution: Look for emergency medical identification around the victim's neck or wrist that could suggest the cause of unconsciousness, if physical signs aren't present.

3. Common Injuries or Illnesses that the School Bus Driver Might Encounter

a. Eye Injuries

(1) Any eye injury is serious, and the bus driver should never attempt to treat an injury of this nature.
(2) In case of eye injury, the eye should be covered with a sterile gauze pad and attended to by a doctor or nurse as quickly as possible. (If feasible, cover both eyes to prevent excessive eye movement.)

b. Vomiting

(1) Vomiting is very seldom preventable, but some relief could be given both before and after vomiting by exposing the person to fresh air.
(2) A partially filled bucket of sawdust or a commercial absorbent is highly recommended to the bus driver for such emergencies.

c. Mouth or face injuries

(1) Most minor internal mouth injuries are self-healing.
(2) An external cut on the mouth or other part of the face should be covered with a sterile gauze pad until the services of the school nurse or a physician can be obtained.

d. Fainting

(1) Fainting is caused by temporary loss of blood to the brain.
(2) Fainting can best be treated by getting the victim's head lower than the trunk of the body.
(3) If a student feels faint, it can best be prevented by having the student put the head between his knees.
(4) Use ammonia ampules to prevent fainting.
(5) Diabetic or epileptic attacks - See Unit X, Section F, Item 4.

20836

e. Falls inside and outside of the bus

(1) The driver should make a diligent search for injuries after a fall.
(2) If an injury has been sustained, the driver should render appropriate first aid treatment.

4. Moving the Injured

a. Do not move injured person before a physician or experienced ambulance crew arrives, unless there is real danger of his receiving further injury by being left at the accident site. If possible, control bleeding, maintain breathing, and splint all suspected fractures before moving. If it is necessary to move the victim, the following methods can be used:

(1) Pull the victim to safety either head first, if possible, or feet first, if necessary, as illustrated. See Figure 34. Victim should not be moved sideways. Be sure that the victim's head and back are protected.
(2) If the victim has to be lifted before a check for injuries can be made, every part of the body should be supported. The body should be kept in a straight line, and should not be bent. See Figure 35.

Figure 34

b. A great amount of care should be used when it becomes necessary to move an injured person, especially if the person is unconscious. There is grave danger of causing further injury to broken bones, aggravating or causing further internal injuries, and causing additional bleeding.

Figure 35

IV. SUMMARY

It is extremely important that the school bus driver should know and use the correct procedures in administering first aid to the injured if the necessity arises.

20837

The school bus driver should keep in mind that first aid procedures apply to immediate needs only, and that he should confine himself to perform only those immediate needs.

This unit is designed to teach the fundamentals of First Aid which deal with the immediate procedures to be used in case of accident. A complete course in First Aid is strongly recommended for every school bus driver.

20838

C. Meat and Poultry Cookery—Continued

Essential learning (Skill and knowledge)	Scope of instruction (Suggested content)	Information (Technical and related)
Braising—Continued		
How to deep fat fry:	Preparation	Cuts of meat and poultry suitable for deep fat frying
The understanding and application of recipes, formulas, and procedures		Fats used:
		Temperature for frying
		Care and storage
		Breakdown or oxidation
		Equipment
	Procedure:	Precautions:
	Seasoning	Thermometers
	Dredging	Thermostats
	Coating	Safe cooking habits
	Temperature	
	Timing	
	Draining	
	Testing for doneness	Methods of testing
		Calculation of costs
How to simmer (boil) meats and poultry:	Explanation of the cooking principle	Cuts of meat and types of poultry suitable for simmering:
The understanding and application of recipes, formulas, and procedures		Age of animal
		Grades
		Variations in terminology:
		Parboiling
		Steaming
		Pressure cooking
		Blanching
		Stewing
		Poaching

	Care in cooking	
	Temperature	
	Timing	
	Testing for doneness	Methods of testing
	Carving	Variations in carving and serving
		Calculation of costs
How to cook stews:	Explanation of cooking principle	Selection of meats for stews
The understanding and application of recipes, formulas, and procedures	Preparation	Equipment
	Procedure:	Variations:
	Seasoning	Irish
	Care during cooking	Fricassees (curry, goulash)
	Temperatures	Brown stews—Ragout
	Timing	
	Finishing	Finishing process:
		Thickening agents
		Calculation of costs

Suggested teaching materials: See items 8, 15, 20, 29, 30, 31, 40, 42, 45, 51, 63, 65, 66, 81, 82, 93, 94, 99, 104 in appendix B.

2059

UNIT X

THE SPECIAL CHILD

128/129 20339

UNIT X

I. TOPIC

The Special Child

II. ORIENTATION

Figure 36

The education of handicapped children has been of great concern to educators for many years. The need to provide increased educational opportunities for these special children is being met through the creation of special schools, equipped with trained teaching personnel to accomplish this goal. Because these special schools must serve a larger attendance area than is normally served by a conventional school, transportation of handicapped children is of major importance.

The problems that arise in transportation of the special child are, in many ways, different and challenging. Each of these children presents different transportation problems. The blind, deaf mute, epileptic, slow learner, diabetic, hemophiliac, emotionally disturbed, and physically handicapped child, all possess different needs in the area of transportation.

This unit will discuss school board policies relevant to the transportation of the special child; proper orientation of parents, teachers, children, and school bus drivers concerning the responsibilities of each party; and some of the common handicaps with which the special child may be afflicted.

III. PRESENTATION

A. **Board Policies** - The school board should establish policies concerning local rules and regulations as to the transportation of special children. These policies should be in addition to the local rules and regulations normally covering the district's transportation program.

1. Thought must be given by the school board to the following factors:

   a. The best type of vehicle to be used to transport the special children.

      (1) Number of children to be transported
      (2) Types of handicaps

20840

b. Maximum size and weight of non-ambulatory children should be established to prevent injury to the child as well as to the driver or his assistant.

c. Proper methods and procedures for control of children.

(1) Establish guidelines for the driver and assistant.
(2) Seek professional advice in establishing said guidelines.
(3) Establish policy for the control of the special child.

d. Require orientation of parents of handicapped children.

(1) Transportation of the handicapped is the responsibility of the district school board.
(2) Parents have responsibilities for preparing their children to be transported each day.

e. Prepare two 3" x 5" cards for each special child.

(1) Cards to be kept:

(a) One card in school office
(b) One card on the school bus

(2) Card should contain necessary information regarding the child.
(3) The suggested information is covered in Section B, Item 6.
(4) Establish policies for transportation to the hospital or recognized medical center for the child who becomes ill while riding the bus.

f. Require drivers to successfully complete school bus drivers' training course.
g. A first aid course is recommended.
h. Establish drivers' assistants - whose main responsibilities would be:

(1) To load and unload children
(2) To maintain control of the children while on the bus.
(3) To look to the needs of each child while bus is in operation.
(4) To assist driver in times of need and for all emergency situations.

2. The board should direct its administrative officers to re-evaluate the programs periodically, and adjust the program as the needs dictate.

B. Parent Responsibilities

1. Know the bus schedule for pick-up and delivery of the child.
2. Have the child "ready" and on time to meet the bus.

a. Fed
b. Properly clothed

20841

c. Necessary supplies and materials to be carried in a pouch or packet
d. All bodily needs performed

3. Know where the child is to be picked up each morning.

   a. On the front porch, or
   b. Inside the house, or
   c. By the front walk

4. In case of inclement weather be certain sidewalks and porches have been cleaned of snow and ice.
5. In the event the child does not plan to attend school on a given day the parent should:

   a. Call school officials in advance, or
   b. Wave the bus on as it nears the house, or
   c. Put a note on the front door.

6. Parents, in cooperation with their doctor, should be responsible for preparing a 3" x 5" card containing:

   a. Student's name
   b. Address
   c. Home phone number and emergency phone number
   d. Nature of child's handicap
   e. Suggested steps to be taken by the driver or his assistant in the event of illness, or injury, while riding the bus.

7. Parents should be available at all times during the school day in the event that they are needed by the school officials.

C. **Teacher Responsibilities**

1. To see that the child is prepared both mentally and physically for the ride on the school bus.
2. Establish teacher-driver communication for the well-being of the child.

   a. Unusual situations may effect the behavior of the child.

      (1) Epileptic seizure or convulsion
      (2) Severe emotional experience

   b. Recommend procedures for beneficial assistance and/or control.
   c. Teacher should check with driver or assistant if any problems have occured.

20342

D. **Child Responsibilities** - The child must know and understand responsibilities, acceptable behavior, and conduct expected of him while riding on the bus to and from the school.

1. The nature and scope of these responsibilities must be determined by such factors as:

   a. Age
   b. Mental capabilities
   c. Nature of handicap

2. The driver should work with the transportation supervisor to seek advice from the school principal, teachers, or special counselor.

E. **Bus Driver and Assistant Responsibilities**

1. Driver and assistant should successfully complete first aid course.
2. Driver and assistant should become acquainted with the particular handicap and the emergency treatment of each child as stated on record card.
3. Driver and assistant should know the safest and most direct route to hospital or recognized medical center.
4. Driver should arrange seating of the children, if possible, to prevent emotional or physical disturbances.

   a. Two deaf mutes side by side may have a tendency to create a control problem.
   b. Some children, by the nature of their handicap, must require an entire seat to themselves.

F. **Various Types of Handicaps Suffered by the Special Child**

1. The blind

   a. May be totally blind
   b. May have only partial sight
   c. Must be guided and protected from objects that would injure them

2. The deaf and the deaf mute

   a. The deaf student may be totally deaf or partially deaf.
   b. The deaf mute is unable to speak or hear.

      (1) Usually relies on sign language and motions
      (2) Usually are taught to become lip readers in the special schools

         (a) Find out how the school wants you to communicate.
         (b) May want the child to lip read rather than use sign language or motion.

20843

c. The deaf mute may be an extremely active and energetic child.

(1) May be very intelligent as well as average or below average.
(2) Is inclined to be more mischievous and emotional.

(a) Special control methods must be used.
(b) Loud commands or stern voice mean nothing to them.

3. The physically handicapped (cerebral palsy, muscular distrophy, polio, etc.)

a. The ambulatory child

(1) Is able to walk. See Figure 37.
(2) May or may not wear braces.
(3) May need some assistance in being seated, and unlocking or adjusting braces.

(a) This is a good example of needed communication between teacher, driver, and assistant.
(b) Do all that is necessary to assure his comfort and safety.

Figure 37

b. The non-ambulatory child

(1) Must use a wheel chair and/or be carried. See Figure 38.
(2) Special seating apparatus may be necessary.
(3) Seat belts are a must for this child.
(4) Usually will need assistance with locking and unlocking braces.
(5) Maximum weight limitation should be established by board policy as child may have to be carried or lifted by the driver or his assistant.

Figure 38

4. The epileptic child

a. May appear normal in every respect.
b. Is subject to seizures or convulsive attacks usually with partial or total loss of consciousness.

20844

c. If seizure takes place on school bus

(1) Steer bus to side of roadway and stop vehicle.
(2) Know and follow directions on child's 3" x 5" card.
(3) Do not restrain the person during his convulsion, but protect him against injury.
(4) Push away near objects.
(5) Try to prevent the victim from biting his tongue by placing an appropriate object between his teeth on one side of the mouth.

(a) Pencil or pen
(b) Piece of wood or branch of tree
(c) Handkerchief
(d) When convulsion is over, loosen clothing about the neck and allow victim to lie flat with head turned to one side.
(e) Provide for undisturbed rest after regaining consciousness.

5. The hemophiliac - A child suffering from the disease of hemophilia (a bleeder).

a. Child is subject to hemorrhage (bleeding) from the slightest bump or bruise.
b. The bleeding may be external or internal.
c. Seek immediate medical help if in doubt concerning possible injury.

6. The emotionally disturbed and the slow learners

a. These children will vary greatly in abilities and response to directions.
b. Usually close supervision by the driver's assistant as to behavior and possible assistance is needed.
c. These children seek affection. The driver and assistant must be friendly and take an interest in each child.
d. Care must be exercised not to show favoritism.

G. Suggested Requirements for the Handicapped Vehicle

1. Maximum capacity should not be more than 28.
2. Seat belts are recommended fastened to the seat and buckled high around the waist of the child.
3. Handicapped vehicle should be identified better than normal school bus.
4. Two-way radios are recommended for the handicapped vehicles.
5. Extra heaters may be required because the handicapped chill easier.
6. Vehicles for the handicapped should have roof ventilators.
7. Rear door may need to be redesigned if used to load and unload children because of the size and type of seal used to prevent exhaust from seeping into the passenger compartment.
8. Tail pipe should be directed to the side in order to prevent exhaust entering the passenger compartment when the door is open.

20845

IV. SUMMARY

The transportation of the special child requires additional knowledge and responsibilities of the school bus driver. It is extremely important that the district school boards adopt policies relating to the transportation of these children. Such factors as:

Types of vehicles to be used
Special equipment needed
Number of children to be transported
Types of illness and handicaps involved

all play an important role in determining the policies and standards to be established. The parents, the school officials, and the school bus drivers and their assistants must have a closer working relationship than is normally required for the transportation of the well and healthy children.

20846

GLOSSARY

1. Accident - Unplanned occurrence that results in property damage or bodily injury.

2. Activate - Start into motion; to make active.

3. Ambulatory - Able to walk about and not bedridden.

4. Big Picture - The overall view of the traffic situation through the eyes of the driver.

5. Blind Intersection - Intersection of two roadways at which the driver approaching on one roadway cannot see the traffic approaching on the other roadway.

6. Blood Vessels - Tubes in which blood circulates. Veins, arteries, capillaries.

7. Braking Distance - The distance the bus travels from the time braking action is applied until the bus comes to a stop.

8. Center Line - The line down the center of the roadway.

9. Cerebral Palsy - A disability resulting from damage to the brain before or during birth manifested by muscular incoordination and speech defects.

10. City Ordinance - An authorative decree or direction set forth by a municipal government.

11. Control - Orderly or prescribed conduct or pattern of behavior; a rule or system of rules governing conduct. To impose order upon; punish; teach.

12. Convulsion - An abnormal violent and involuntary contraction or series of contractions of the muscles.

13. Cruising Gear - The highest speed gear of any one transmission.

14. Deactivate - To make inactive; to stop.

15. Diabetes - Any of various abnormal conditions characterized by the secretion and excretion of excessive amounts of urine.

16. Discipline - See No. 11 - CONTROL

17. Divided Highway - Multi-lane highway. The lanes that are open for traffic in one direction are separated from the lanes provided for traffic in the opposite direction by a median strip or a physical barrier.

20847

18. Downshift - Shift from a higher gear to a lower gear.

19. Epilepsy - A disorder of the central nervous system typically manifested by convulsive attacks.

20. Four-Way Hazard Flashers - Are activated by hazard switch. Activates all turn signals simultaneously to warn approaching traffic of road hazard.

21. Freeway - "A divided multi-lane highway for through traffic with all cross roads separated in grade and with full control of access."

22. Handicapped Vehicle - A special designed vehicle usually with larger doors, rear steps, seat belts, support rails, and extra padding to insure safety during the transportation of the handicapped child.

23. Hemophilia - Hereditary tendency to uncontrollable bleeding.

24. Highway - "The entire width between the boundary lines of every way open to the use of the public as a thoroughfare for purposes of vehicular travel."

25. Inspection Decal - An emblem issued by the Ohio State Highway Patrol to be displayed on each side of the bus. Issued by patrol after a safety inspection is made of the bus by the patrol and the bus meets the necessary standards.

26. M.P.H. - Miles Per Hour

27. Marker Lights (Clearance Lights) - The amber lights located on upper front corners of bus; red lights on upper rear corners.

28. May - to be able; optional.

29. Motor Vehicle - "Every vehicle propelled or drawn by power other than muscular power or power collected from overhead electric trolley wires, except road rollers, traction engines, power shovels, power cranes, and other equipment used in construction work and not designed for or employed in general highway transportation, hole-digging machinery, well-drilling machinery, ditch-digging machinery, farm machinery, threshing machinery, hay-baling machinery, and agricultural tractors and machinery used in the production of horticultural, floricultural, agricultural, and vegetable products."

30. Muscular Dystrophy - A hereditary disease characterized by progressing wasting of muscles.

31. Must - Mandatory; essential; shall.

32. O.R.C. - Ohio Revised Code

33. Polio - An acute infectious virus disease characterized by fever, motor paralysis, and atrophy of skeletal muscles.

20848

D. Fish and Shellfish Cookery

2060

34. Preventive Maintenance - Maintenance performed with the intent to reduce breakdowns.

35. Roadway - "That portion of a highway improved, designed, or ordinarily used for vehicular travel, except the berm or shoulder. If a highway includes two or more separate roadways, the term 'roadway' means any such roadway separately but not all roadways collectively."

36. R.P.M. - Revolution Per Minute of Engine.

37. Seizure - A sudden attack.

38. Shall - Mandatory; must.

39. Should - Urgent request.

40. State Law - A principle governing action or procedure imposed by the Ohio State General Assembly.

41. State Regulation - A principle governing action or procedure imposed by the State Board of Education.

42. Syncro-mesh Transmission - In a syncro-mesh transmission, there is a built-in unit that brings gears into position of alignment for easy shifting as soon as clutch pedal is depressed.

43. Traffic Control Device - "All signs, signals, markings, and devices placed or erected by authority of a public body or official having jurisdiction, for the purpose of regulating, warning, or guiding traffic, including signs denoting names of streets and highways."

44. Vehicle - "Every device in, upon, or by which any person or property may be transported or drawn upon a highway, except devices moved by power collected from overhead electric trolley wires, or used exclusively upon stationary rails or tracks, and except devices other than bicycles moved by human power."

45. Warning Lights (Flasher Lights) - Red lights alternately flashing; used for student pick-up and student discharge.

46. Will - A command; an order.

ABSTRACT - Ohio State staff prepared this manual to assist prospective school bus drivers in becoming familiar with the transportation laws and regulations, to acquaint them with the proper techniques of school bus driving, and to impress upon them the magnitude of their responsibilities. Five units included are: (1) The School Bus Driver, (2) Pupil Transportation Laws and Regulations in Ohio, (3) Digest of Motor Vehicle Laws in Ohio, (4) School Bus Orientation, and (5) Driving Fundamentals. Most sections in the units provide content, orientation material, presentation suggestions, and a summary. A limited number of illustrations are used throughout. A glossary and bibliography are included. (GEB)

PREFACE

The purpose of this manual is: (1) to assist prospective school bus drivers in the State of Ohio to become familiar with the transportation laws enacted by the Ohio General Assembly and the transportation laws and regulations adopted by the State Board of Education, (2) to acquaint the drivers with the best known techniques of school bus driving and (3) to impress upon the drivers the magnitude of their responsibilities and the necessity to observe every safety precaution.

A combined effort by the personnel of the Transportation Section of the Division of School Finance and the Trade and Industrial Education Section of the Division of Vocational Education made the writing and publishing of this manual possible.

Special acknowledgement is given to the following individuals for their contributions:

I. WRITERS:

John Burkam, Supervisor, Foundation Section, State Department of Education

Dudley Lee, Area Coordinator, Area #17, State Department of Education

Zygmont Rataiczak, Area Coordinator, Area #28, State Department of Education

Robert Seward, Area Coordinator, Area #21, State Department of Education

Roger Smith, Area Coordinator, Area #19, State Department of Education

Robert Whisman, Consultant, School Bus Driver Education, Trade and Industrial Education Section, State Department of Education

UNIT I

THE SCHOOL BUS DRIVER

20859

UNIT I

I. TOPIC

The School Bus Driver

II. ORIENTATION

The school bus driver is the most important cog in the school transportation program. The drivers of school buses transporting boys and girls to and from school should know the qualifications and characteristics which are essential for them to fulfill their job safely and efficiently. This unit will deal with the necessary steps required to be certified as a school bus driver and driver qualifications and characteristics.

III. PRESENTATION

A. Certification Steps

1. Apply to school district for job application form and arrange for a personal interview.
2. Check school bus driver physical disqualification sheet.

Form 1

PHYSICIAN'S SCHOOL BUS DRIVER DISQUALIFICATION SHEET

Applicants shall be disqualified if:

(a) Applicant's heart and/or circulatory system are abnormal.

1) Diastolic Blood Pressure is less than 50 or more than 100
2) Coronary Insufficiency or evidence of coronary artery disease
3) History of Myocardial Infarction
4) History of Congestive Heart Failure
5) History of Cerebral Vascular Accident

(b) Applicant is taking medication to correct high blood pressure or drugs with sedative or other reactions which will impair physical or mental functions.

(c) Applicant has diabetes.

(d) Applicant's hearing must be a minimum of 10/15 by whispered voice. Hearing aid is permissible.

(e) Applicant's vision is less than 20/200 uncorrected in each eye.

(f) Applicant's vision is less than 20/30 corrected in each eye.

(g) Applicant cannot readily distinguish red, green, and yellow.

(h) Applicant's lateral peripheral field of vision is less than 70° in each eye.

20860

(i) Applicant does not have reasonable use of four extremities with thumb and at least two fingers on each hand. Applicant has artificial limb.

(j) Applicant has or has had a convulsive disorder.

(k) Applicant has speech defect which would make it impossible to give clear directions or commands.

(l) Applicant is known to have a mental disorder, drug addiction or alcoholism.

(m) Applicant shows evidence of active pulmonary tuberculosis, or other communicable diseases.

(n) Applicant has other defects which would affect his ability to drive a school bus.

3. Arrange for a tuberculin skin test or chest x-ray. (Performed within the past year)
4. Arrange for a physical examination. (Medical Examination Report Form for School Bus Drivers must be used.) See Form 2, Page 5.

   a. Obtain form from school district
   b. Payment for examination (Shall be paid by county, city or exempted village board)
   c. Designate examining physician(s) (Shall be designated by county, city, or exempted village board)
   d. Required each school year

5. Arrange with local State Highway Patrol Post Examining Station for written tests and driving examination. Secure a copy of the completed medical examination form from school district administrator and take to testing center.
6. Apply to county superintendent, city superintendent, or exempted village superintendent, whichever is applicable for the driver's certificate.

   a. Check local policy
   b. Required each school year

B. Physical Qualities

1. Vision

   a. Driver must have 20/30 vision or better in each eye - with or without glasses.

      (1) See clearly at 20 feet what the average person can see at 30 feet
      (2) Driver should have his vision checked by a qualified person each year.
      (3) A person shall not drive a school bus until visual defects are corrected.

Form T8 (Revised 1-20-69)

HIGHWAY PATROL COPY

20862

b. Peripheral vision or field vision

(1) The angle to the left and to the right that a person can see when looking straight ahead is known as field of vision.

Figure 1

(2) The driver must have a field of vision of 140° or more.

c. Color blindness

(1) A driver must be able to distinguish colors in order to observe traffic lights, stop lights, warning signals.
(2) The colors used are red, green, amber, and yellow.

(a) Amber is used on traffic signals, directional signals, and vehicle clearance lights.
(b) Yellow is used for traffic control signs.

d. Depth perception

(1) The ability to judge the size, shape, distance, and rate of motion of an object is known as depth perception.
(2) Judgment of depth is required in important situations such as:

(a) Overtaking and passing another vehicle
(b) Turning in traffic
(c) Parking in limited spaces
(d) Judging relative sizes and distances of objects and spaces ahead

e. Night vision

(1) The effects of darkness and light glare on an individual's eyes determine the ability to drive safely at night.

20863

(2) Those qualities necessary for good night vision are:

(a) Dark adaptation - the ability of a person to see after his eyes have been subjected to darkness.

(b) Glare recovery - the ability of a person's eyes to re-adjust normally after passing glaring lights.

(c) Glare resistance - the measure of a driver's ability to see when facing the glare of lights from an approaching vehicle.

Figure 2

2. Hearing

a. A school bus driver's hearing must be a minimum of 10/15.

b. Good hearing enables him to hear warning bells, signals, mechanical trouble, and other sounds relating to traffic or safety in driving.

(1) Hearing a whispered voice 10 inches away which the average person can hear 15 inches away.

(2) Hearing aid is permissible.

3. The school bus driver should have sufficient strength to handle the bus confidently regardless of the driving situations.

4. Reaction time

a. The reaction time is the length of time it takes a driver to recognize a hazard, determine evasive action, and perform the necessary action.

(1) The driver's braking reaction time should not exceed one second.

(2) Quick reaction time may help to avoid a potential accident situation.

b. Other important reaction times

(1) Turning

(2) Acceleration

(3) Deceleration

C. Desired Mental and Emotional Qualities of a School Bus Driver

1. Positive attitude rather than negative

20864

2. Friendly personality
3. Emotional stability is a must

   a. Calmness under stress
   b. Even temperament

4. Alert and safety minded at all times
5. Patient and dependable
6. Honest and fair

D. Character Traits

1. Have good oral expression - free from derogatory remarks and abusive language.
2. The driver should help all children feel that they belong, are respected, and share in the rights and privileges as well as the responsibilities of the group. Children of all ages regardless of race, color, creed, or economic status need to feel socially acceptable.
3. Refrain from the use of tobacco while on duty.
4. Abstain from the use of any alcoholic beverage preceding and while driving a school bus.
5. Drivers should like and understand children.

E. Personal Hygiene

1. Cleanly shaven.
2. Maintain body cleanliness.
3. Clean and suitable wearing apparel for the occasion.

IMPROPER

PROPER

IMPROPER

PROPER

Figure 3

20865

IV. SUMMARY

School bus drivers must be alert to everything around them. Certainly their health must be given top priority, for without passing all the physical tests they cannot qualify as bus drivers.

Their personalities, character traits, and personal hygenic habits all lead to good mental health conditions which are necessary to handle a group of children, and face the public.

PUPIL TRANSPORTATION LAWS AND REGULATIONS IN OHIO

Introduction

Pupil transportation in Ohio is governed by the Revised Code of Ohio, by Regulations adopted by the State Board of Education, and by policy adopted by school district boards of education.

A Board of Education is limited to powers expressly granted by statute and those necessary to carry into effect the powers expressly granted. Where discretionary powers are vested by statute in a Board of Education, such discretion is limited only by Judicial Review in case of fraud or abuse of discretion (1928 OAG 1714).

These Regulations have been adopted by the State Board of Education with the advice and consent of the Director of Highway Safety.

20868

UNIT II

SECTION ONE

I. TOPIC

Transportation Responsibilities of the State Agencies

II. STATE DEPARTMENT OF EDUCATION

A. Construction and Design of School Buses (Sec. 4511.76(A) O.R.C.)

The State Department of Education shall adopt and enforce standards of construction, design and equipment of all school buses owned and/or operated by public school districts or under contract with a public school district. (See Ohio School Bus Minimum Standards)

NOTE: All other buses are regulated by the Director of Highway Safety. (See Sec. 4511.76(B) O.R.C.)

B. Operating Regulations (Sec. 4511.76(A) O.R.C.)

The State Department of Education shall adopt and enforce regulations which govern pupil transportation administration and operation procedures.

NOTE: All other buses are regulated by the Director of Highway Safety. (See Sec. 4511.76(B) O.R.C.)

C. Fiscal Responsibilities (Sec. 3317.051 O.R.C.)

1. The State Board of Education shall determine by formula the total amount of money approved for each district in which the transportation meets the regulations prescribed by it to secure an efficient and economical program of pupil transportation. (Sec. 3327.012 O.R.C.)
2. The State Board of Education shall adopt a formula for assistance to eligible districts for the purchase of school buses. (Sec. 3317.07 O.R.C.)

D. Area Coordinator (Transportation)

1. The Area Coordinator (Transportation) has the following responsibilities:

   a. Designate collection points (Sec. 3327.01 O.R.C.)
   b. Establish routes, schedules, and utilization of equipment that has been recommended by each board of education to whatever extent is feasible. (Sec. 3327.011 O.R.C.)

III. COUNTY BOARD OF EDUCATION, CITY AND EXEMPTED VILLAGE SUPERINTENDENTS

A. The County Board or City or Exempted Village Superintendent shall provide annual physical examinations for school bus drivers. (Sec. 3327.10 O.R.C.)

20869

B. The County Board or City or Exempted Village Superintendent shall issue a drivers' certificate upon determining that each school bus driver and substitute driver has met the requirements as established by the Ohio Revised Code and these regulations. (See School Bus Driver)

C. The County Board of Education or City or Exempted Village Superintendent may revoke such certificate:

1. When the school bus driver fails to meet the requirements established by these regulations. (See School Bus Driver)
2. When a driver is found guilty of improper conduct or has failed to notify the authorities of all traffic violations and convictions; or has failed to comply with any laws of the State of Ohio, Regulations of the State Board of Education, or policies of the school district of employment.

D. The county, city or exempted village superintendent shall provide at least one (1) annual safety workshop for transportation personnel.

IV. LOCAL, CITY AND EXEMPTED VALLAGE SCHOOL BOARD RESPONSIBILITIES

A. District Boards of Education:

1. Are responsible for the operation of the school transportation program. The Board of Education may delegate the authority for direct control to the superintendent or other administrative employee.
2. Shall provide transportation for all pupils so crippled that they are unable to walk regardless of the distance to a school where the State Board of Education prescribes minimum standards. (Sec. 3327.01 O.R.C.)
3. Shall provide transportation for all resident elementary children who live more than two miles from the public school to which they are assigned or to the non-public school to which they attend. (Sec. 3327.01 O.R.C.)
4. Shall recommend to the Area Coordinator (Transportation) routes, schedules, and utilization of transportation equipment. (Sec. 3327.011 O.R.C.)
5. Shall adopt a time schedule and put in force no later than ten days after the beginning of the school term. (Sec. 3327.01 O.R.C.)

B. District Boards of Education may:

1. Provide transportation for high school pupils. (Sec. 3327.01 O.R.C.)
2. Provide transportation for any elementary or high school pupils residing any distance. (Sec. 3327.01 O.R.C.)
3. Pay a parent or guardian in lieu of transporting an eligible pupil when the board deems such transportation impractical. (Sec. 3327.01 O.R.C.)
4. Procure accident insurance on school buses. When carried by the Board, the amount of liability insurance shall not exceed five hundred thousand dollars. (Sec. 3327.09 O.R.C.)

20870

5. Designate depots to gather pupils for transportation purposes. If the board designates such a depot, they shall provide a shelter. (Sec. 3327.03 O.R.C.)
6. Maintain turn-around points. (Sec. 3327.12 O.R.C.)
7. Make cooperative agreements with recreation commissions for the use of school buses to transport students taking part in summer recreation programs. (OAG 67-081-1967)
8. Assess a fee, not to exceed the actual cost, for transportation to and from established educational exhibits and programs during summer months, Saturdays, and holidays.
9. Use buses for summer or auxiliary service programs for resident pupils sponsored by district boards of education.

NOTE: Transportation operational expense records must be maintained for sections 8 and 9 above. Such expenses are not reimbursable through state foundation monies.

10. Permit the use of school buses in the event of civil emergency.

C. **Boards of Education shall not:**

1. Transport pupils to or from any school which practices discrimination against any person on the grounds of race, color, religion, or national origin. (Sec. 3327.01 O.R.C.)
2. Pay a parent more than the state average cost per pupil for transporting pupils in the previous school year, when the board pays the parent or guardian in lieu of transporting a pupil eligible for such service. (Sec. 3327.01 O.R.C.)
3. Transport pupils residing within another district without that school district's written consent. (Sec. 3327.05 O.R.C.)
4. Transport pupils to a school which does not meet the minimum standards prescribed by the State Board pursuant to Division (D) of Section 3301.07 of the Revised Code. (Sec. 3321. O.R.C.)

D. **District Boards of Education Are Not Required to Provide Transportation For:**

1. Non-public pupils who attend a school which requires more than 30 minutes of direct travel time as measured by a school bus from the collection point to the pupil's school of attendance. (Sec. 3327.01 O.R.C.)
2. Pupils where it is impractical to provide such service with a school bus. (Sec. 3327.01 O.R.C.)
3. Pupils, when in the judgment of such board of education and confirmed by the State Board of Education, such transportation is unnecessary or unreasonable. In determining the necessity for transportation, availability of facilities and distance to school shall be considered. (Sec. 3327.01 O.R.C.)

20871

UNIT II

SECTION TWO

I. TOPIC

Transportation Personnel Responsibilities

II. THE TRANSPORTATION ADMINISTRATOR (SUPERINTENDENT OR SUPERVISOR)

A. A transportation administrator may be the superintendent, local superintendent, principal, transportation supervisor or any other person designated by the Board of Education to administer the transportation program. The Board of Education may delegate the administration, but not its legal responsibilities for, pupil transportation.

B. The transportation administrator shall provide safe school buses by:

1. Assuring that all school buses meet or exceed the "Ohio School Bus Minimum Standards" in effect at the time of purchase.
2. Providing a quality, continuing maintenance program.
3. Providing for the pre-inspection and completion of Form T-30 (O.D.E.) for all school buses before the annual Ohio State Highway Patrol inspection.
4. Assuring that all school buses are presented for inspection.
5. Providing for regular safety inspections and correcting immediately all deficiencies noted.

C. Is responsible for recommending to the Board of Education the names of qualified applicants for employment.

D. Shall see that all school bus drivers are instructed as to routes, time schedules, duties, laws, regulations, and school district policies related to pupil transportation.

E. Is responsible for seeing that all drivers meet the requirements of the laws of Ohio and Ohio Department of Education regulations before driving a bus with pupils on board. He shall make arrangements for the basic school bus driver's education program. (See School Bus Driver)

F. He shall maintain a school district map or route description system indicating all routes, pick-up points, names of students by bus by stop, the grade and school of attendance, and a route time schedule.

G. He shall administer the transportation policies and procedures relating to pupil behavior.

20872

H. He shall, in the case of city and exempted village school districts, provide for one (1) annual safety workshop for transportation personnel. Local school district transportation administrators shall require the transportation personnel to attend one (1) annual county sponsored safety workshop.

I. He shall be responsible for maintaining accurate records of:

1. Vehicle inventory
2. Daily miles traveled
3. Students transported
4. Annual operating costs by vehicles for the regularly scheduled trips.

J. He shall maintain accurate record of annual miles and costs for non-routine use of school buses.

K. He shall provide all information as required by the Ohio Department of Education.

III. THE SCHOOL BUS DRIVER

A. To be employed as a school bus driver the following requirements must be met:

1. Be at least 21 years of age.
2. Be of good moral character.
3. Be physically qualified as determined by an annual physical examination meeting the criteria established by Ohio Department of Education Form T-8.
4. Prior to testing by the Ohio State Highway Patrol, be trained in the operation of a school bus and have a knowledge of the Transportation Laws and Regulations.
5. Hold a current Ohio Chauffeur's License marked "School Bus Operator".
6. Hold a current bus driver's certificate issued by the County Board of Education or City or Exempted Village Superintendent.
7. Shall be required to satisfactorily complete the State Department of Education's Basic School Bus Driver Education Program within the first year of employment as a school bus driver.
8. Attend all safety workshops and meetings as required by district administration.

B. It is recommended that boards of education not employ any person as a school bus driver who has passed his 65th birthday.

C. No person shall be employed as a bus driver who is addicted to alcohol, narcotics or other drugs of a sedative nature.

D. The bus driver shall not use or permit the use of tobacco while pupils are on the bus.

E. The use of stimulants, sedatives or any other substance which will affect the bus driver's judgment and driving ability during his routes is prohibited.

20873

UNIT II

SECTION THREE

I. TOPIC

Operational Regulations

II. SCHOOL BUS OPERATIONS AND DRIVING PROCEDURE

A. The school bus driver shall make a daily inspection to determine if the bus is in safe operating condition.
The following items should be checked:

1. Air Brakes - (a) Drain water from air reservior tanks
   (b) Air pressure indicators
2. Brake Pedal - Travel on hydraulic brake systems
3. Steering
4. Tires and Wheel Lugs
5. Engine Oil Level - Must not be below "add" mark
6. Radiator Coolant Level
7. Emergency Equipment
8. Heaters and Defrosting Equipment (seasonal)
9. Lights
10. Instruments and Gauges
11. Horn
12. Windshield Wipers and Washers
13. Interior Cleanliness
14. Glass Areas - Clear vision to front, sides and rear.

B. All items checked and found deficient shall be reported to responsible authority. Mechanical defects shall be reported in writing.

C. In no event shall a bus be driven backward on school grounds while children are being loaded or unloaded.

D. When departing from the loading area, buses shall maintain a safe interval. No passing shall be permitted in the loading area.

E. Bus drivers shall maintain a distance of 300 feet behind any preceding moving vehicle while traveling on the highway at normal speed.

F. School buses operating on divided highways or highways with four or more traffic lanes shall receive and discharge all school children on their residence side of the highway. (Sec. 4511.75(C) O.R.C.)

G. Before receiving and discharging pupils on the highway, the bus shall be driven to the right side of the paved or traveled portion of the roadway and brought to a full stop.

20874

H. The bus driver shall be the only operator of the service entrance door. The door shall not be opened to load or unload pupils until traffic has cleared the the bus or come to a complete stop in all directions.

I. Warning flasher lights shall be used to prewarn other motorists of the intention of the bus to stop for the singular purpose of loading or unloading pupils. The lights shall remain in operation during the total time the bus remains stationary.
Warning flasher lights shall not be used:
(1) When stopped for railroad grade crossings.
(2) While stopped on traveled highway used for loading and unloading pupils at school locations.
(3) At turn arounds

J. Driver shall not use service door control to activate warning flasher lights. Door must remain in complete "locked" position while bus is in motion.

K. Four-way hazard lights may be used at bus turn arounds.

L. The bus shall not be started in motion until after pupils who have been discharged from the bus have reached a place of safety on their residence side of the road. (Sec. 4511.75(D) O.R.C.)

M. The driver shall use the established route and make stops as designated by the board of education or the administrator who is authorized to designate such stops.

N. The driver shall operate the bus on the approved time schedule and shall wait for pupils if running ahead of schedule.

O. School buses shall be brought to a stop before crossing railroad grade crossings and while so stopped, the driver shall listen through an open door or open window and look in both directions along the track. He shall not proceed until safe to do so.
The driver shall cross only in such gear of the vehicle that there will be no necessity for changing gears during the crossing. (Sec. 4511.63 O.R.C.)

P. The school bus driver shall require silence of all pupils at all railroad crossings. All school bus drivers shall obey all state and local traffic laws.
SPEED (Sec. 4511.21 O.R.C.)
No person shall operate a motor vehicle, trackless trolley, or streetcar in and upon the streets and highways at a speed greater or less than is reasonable or proper, having due regard to the traffic, surface, and width of the street or highway and any other conditions, and no person shall drive any motor vehicle, trackless trolley, or streetcar in and upon any street or highway at a greater speed than will permit him to bring it to a stop within the assured clear distance ahead.

20875

The maximum speeds for school buses are:

1. 20 MPH in school zones (during restricted hours).
2. 25 MPH inside corporations, except on state routes, through highways outside business districts and alleys.
3. 35 MPH on state routes or on through highways within municipalities outside business districts.
4. 50 MPH on controlled-access highways and expressways within municipal corporations (day or night).
5. 55 MPH on freeways outside municipal corporations (day or night).
6. 15 MPH on alleys within municipal corporations.

Section 4511.22 O.R.C.

No person shall operate a vehicle, trackless trolley, or streetcar at such a slow speed as to impede or block the normal and reasonable movement of traffic, except when reduced speed is necessary for safe operation or to comply with law.

Q. A school bus shall not be refueled while the engine is running.

R. The driver shall not leave the bus until the brakes are set, the engine stopped and the ignition key is removed.

III. TRAFFIC REGULATION

A. No school bus shall be stopped, or shall be turned so as to proceed in the opposite direction, upon any curve or upon the approach to or near the crest of a grade, where such vehicle cannot be seen by the driver of any vehicle approaching from either direction within 500 feet. (Sec. 4511.37 O.R.C.)

B. The school bus driver shall permit other vehicles to pass when a line of traffic accumulates at the rear of the bus. (Sec. 4511.75(A) O.R.C.)

C. A school bus shall not be parked within the limits of the highway right-of-way. (Sec. 4511.66 O.R.C.)

IV. PUPIL BEHAVIOR

A. While riding on a school bus, reasonable conversation is permissible and may be regulated by the driver.

B. The driver shall be in charge of the bus at all times and shall be responsible for order. He should not exclude a pupil from the bus. The driver shall report the unmanageable pupil to the proper authority. Disorderly conduct shall be sufficient reason for refusing transportation service to any pupil.

20876

C. Whenever it becomes necessary to refuse a pupil transportation, the school authorities shall notify the parents of such refusal with a full explanation. Until such time as the school authorities have received assurance from the parents of future good conduct on the part of the pupil and the bus driver has been so advised, the driver shall not permit the pupil to board the bus.

V. SCHOOL BUS ACCIDENT REPORTING

The bus driver shall report any accident involving a school bus to the police agency within whose jurisdiction the accident has occurred and to the superintendent of schools.

The superintendent of the school district whose bus was involved in an accident shall report such accident on Department of Education Form T-10 within fifteen days from the time of the accident.

A copy of each report shall be retained in district file for a period of five years.

Definition of Motor Vehicle Accident

(a) Any incident or occurrence involving a school bus operated by or under contract to a school district which results in a fatality, an injury, or damage to any motor vehicle or property.

(b) Any action taken by a bus driver employed by a school district which contributes directly to any fatality, injury or damage to any motor vehicle or property.

VI. LOADING AND UNLOADING AT SCHOOL FACILITIES

A. When it is necessary to load or unload pupils off the school grounds, the bus shall be stopped and positioned so that pupils do not cross the road to get to or from the bus.

B. All warning flasher lights shall be turned off while loading and unloading at the school building in order that traffic may proceed without interference.

C. Bus drivers shall remain on the bus while pupils are loading and unloading.

D. Pupils waiting to board buses shall be supervised by school authorities.

VII. SCHOOL BUS STOPS

The board of education shall approve all bus stops. School bus stops shall be limited so far as possible. Pupils may be required to walk to a designated bus stop.

VIII. PUPIL LOAD

Pupils may be assigned seats. The number of pupil standees shall not exceed 10% of the number seated.

20877

F. Ground and Variety Meat Cookery

Essential learning (Skill and knowledge)	Scope of instruction (Suggested content)	Information (Technical and relate ')
How to prepare ground and chopped 'meat dishes: The understanding and application of recipes, formulas, and procedures	Preparation of various types: Chopped meat: Raw Cooked Hashes	Economy factors: Use of leftovers Use of meat trimmings Storage and care Bacteriology and sanitation Equipment and tools
	Procedure: Seasoning Temperature Time	Sauces, gravies, stocks Methods of serving: Garnishes
How to prepare variety meats: The understanding and application of recipes, formulas, and procedures	Preparation of each kind of glandular or variety meat	Kinds: Liver Kidney Sweetbreads Tongue Brains Tripe Heart Care in storage Nutritive value, cost factor, acceptability, or regional preference Variety of uses
	Procedure: Seasoning Cooking process Temperature Time	

Suggested teaching materials: See items 8, 10, 20, 31 in appendix B.

2063

IX. NON-ROUTINE USE OF SCHOOL BUSES

A. The regulations governing non-routine use of buses apply to vehicles owned and operated by boards of education or under contract to a board of education. The regulations pertain to summer use of buses as well as during the regular school year.

B. Trip Permit
City, exempted village and local superintendents shall issue a trip permit for each co-curricular use of a school bus. The permit shall provide the following information: (1) date of trip; (2) destination of trip; (3) purpose of the trip; (4) name of the school district; (5) driver's name; (6) bus registration number; (7) total miles of trip; (8) superintendent's signature.

C. School buses may be used to transport pupils to and from any event that is a planned part of the classroom or the educational program. Expenses may be paid from the general fund.

D. School buses may be used to transport participating pupils to and from any co-curricular activity programs approved by the district boards of education. Pupil participants living on the most direct route to the activity from the school may be picked up and discharged as far as is practical. These expenses shall not be paid from the general fund.

E. Each event that requires the use of more than five school buses to transport participants to and from a co-curricular activity shall require a resolution by the district board of education.

F. School buses shall not be used for pleasure trips.

G. School buses shall not be used to transport spectators, either student or adult.

H. Adults may be transported to assist teacher on educational trips, if approved by the superintendent.

I. Students may not be transported to observe college or professional games - i.e., football team, band, etc.

J. Buses shall not be used for combination trips such as taking students to a museum in the morning and to view a football contest in the afternoon.

K. No pupil charge may be made for transporting pupils in any school bus to and from regular day classes and other co-curricular trips on school days. This applies equally to board-owned buses and privately owned buses operated under contract with a board of education.

20878

L. A fee not to exceed actual costs may be assessed for transportation to and from established educational exhibits and programs during summer months, Saturdays, and holidays.

M. Board-owned school buses may be used for trips outside the state, provided the entire round trip does not exceed one hundred twenty miles from the sending school. Contract buses are excluded from interstate trips under Interstate Commerce Commission. (Administrative Ruling No. 80, Sec. 203(b) 1 & 9)

N. School buses may be used by government agencies in Ohio for use during emergencies. (Example: National Guard Reserves transported to riot area.)

UNIT II

SECTION FOUR

I. GENERAL REGULATIONS

A. **Transportation of Special Equipment.** When it is necessary to transport special equipment, each passenger on the bus must be seated.

B. **Emergency Drills.** The transportation supervisor and/or the bus driver shall conduct a minimum of two rear door emergency evacuation drills on each school bus each year. Drills shall be conducted on the school grounds, or off the highway area. Responsible pupils should be assigned to open the emergency door and assist younger pupils from the bus.

C. **Forbidden Cargo.** While students are riding on the bus, animals, firearms, ammunition, explosives, or other dangerous materials or objects which may interfere with safe operation of the vehicle shall not be transported.

D. **Unauthorized Passengers.** No unauthorized passengers shall be transported on a school bus. (Example: Pre-school age children.)

20879

STATE LAWS PERTAINING TO PUPIL TRANSPORTATION

SEPARATE FACILITIES FOR MENTALLY RETARDED CHILDREN

3313.88

The board of education of any school district may establish separate schools or facilities for the instruction of mentally retarded children and may:

(A) Expend school funds in the establishment of such schools or facilities;

(B) Provide for the transportation of any such pupils to and from the schools or facilities established under this section;

(C) Contract with the child welfare board, the board of county commissioners, or any municipal corporation to provide training for mentally retarded children upon whatever terms the contracting parties agree upon for the division of the cost of maintaining and operating the schools or facilities for such pupils. (127 v H568. Effective 9-16-57.)

Board may contract for transportation of mentally retarded pupil to public school in another district, but not to private school.

TRANSPORTATION OF PUPILS; EXCESS COST FROM FEDERAL FUNDS

3327.01

In all city, exempted village, and local school districts where resident elementary school pupils live more than two miles from the school for which the state board of education prescribes minimum standards pursuant to division (D) of section 3301.07 of the Revised Code and to which they are assigned by the board of education of the district of residence or to and from the non-public school which they attend the board of education shall provide transportation for such pupils to and from such school except when, in the judgment of such board, confirmed by the state board of education, such transportation is unnecessary or unreasonable.

In all city, exempted village, and local school districts the board may provide transportation for resident high school pupils to and from the high school to which they are assigned by the board of education of the district of residence or to and from the non-public high school which they attend for which the state board of education prescribes minimum standards pursuant to division (D) of section 3301.07 of the Revised Code.

In determining the necessity for transportation, availability of facilities and distance to the school shall be considered.

20881

A board of education shall not be required to transport elementary or high school pupils to and from a non-public school where such transportation would require more than thirty minutes of direct travel time as measured by school bus from the collection point as designated by the coordinator of school transportation, appointed under section 3327.011 of the Revised Code, for the attendance area of the district of residence.

Where it is impractical to transport a pupil by school conveyance, a board of education may, in lieu of providing such transportation, pay a parent, guardian, or other person in charge of such child, an amount per pupil which shall in no event exceed the average transportation cost per pupil, such average cost to be based on the cost of transportation of children by all boards of education in this state during the next preceding year.

In all city, exempted village, and local school districts the board shall provide transportation for all children who are so crippled that they are unable to walk to and from the school for which the state board of education prescribes minimum standards pursuant to division (D) of section 3301.07 of the Revised Code and which they attend. In case of dispute whether the child is able to walk to and from the school, the health commissioner shall be the judge of such ability.

When transportation of pupils is provided the conveyance shall be run on a time schedule that shall be adopted and put in force by the board not later than ten days after the beginning of the school term.

A district receiving a payment pursuant to division (B) of section 3317.02 of the Revised Code is not eligible for reimbursement of transportation operating costs or eligible for school bus purchase subsidy payment pursuant to section 3317.06 of the Revised Code, except for transporting children who are crippled and for transporting pupils attending non-public schools.

The cost of any transportation service authorized by this section shall be paid first out of federal funds, if any, available for the purpose of pupil transportation, and secondly out of state appropriations, in accordance with regulations adopted by the state board of education.

No transportation of elementary or high school pupils shall be provided by any board of education to or from any school which in the selection of pupils, faculty members, or employees, practices discrimination against any person on the grounds of race, color, religion, or national origin. (132 v S 451. Effective 2-29-68. 132 v H 823, H1; 131 v S 365)

20382

3327.011

Coordinators of school transportation shall be appointed according to provisions of section 3301.13 of the Revised Code to assure that each pupil, as provided in section 3327.01 of the Revised Code, is transported to and from the school which he attends in a safe, expedient, and economical manner using public school collection points, routes, and schedules.

In determining how best to provide such transportation, where persons or firms on or after April 1, 1965, were providing transportation to and from schools pursuant to contracts with persons or agencies responsible for the operation of such schools, a coordinator or the board of education responsible for transportation in accordance with section 3327.01 of the Revised Code shall give preference if economically feasible during the term of any such contract to the firm or person providing such transportation. The boards of education within the county or group of counties shall recommend to the coordinator of transportation routes, schedules, and utilization of transportation equipment. The coordinator, upon receipt of such recommendations, shall establish transportation routes, schedules, and utilization of transportation equipment, following such recommendations to whatever extent is feasible. The appeals from the determination of the coordinator shall be taken to the state board of education. (132 v H 455. Effective 12-11-67 131 v S 365)

DESIGNATION OF DEPOTS

3327.03

The boards of education of city, exempted village, and local school districts may by resolution designate certain places as depots from which to gather children for transportation to school, when such districts provide transportation. The places designated as depots shall be provided with a shelter and be made comfortable during cold and stormy weather.

TRANSPORTATION OF NONRESIDENT PUPILS

3327.05

The board of education of any school district shall not provide transportation for any pupil who is a school resident of another school district unless the board of the district of the pupil's residence has given its written consent thereto. If the board of any school district files with the state board of education a written complaint that transportation for resident pupils is being provided by the board of another school district, contrary to this section, the state board of education shall make an investigation of such complaint. If the state board of education finds that transportation is being provided contrary to this section it may withdraw from state funds due the offending district any part of the amount that has been approved for transportation pursuant to section 3317.051 of the Revised Code. (126 v 288. Effective 10-1-56.)

20883

SCHOOL BUSES AND DRIVERS

Purchase of School Buses; Terms; Bidding

3327.08

Boards of education of city school districts, exempted village school districts, local school districts, joint high school districts, and joint vocational school may purchase on on individual contract school buses and other equipment used in transporting children to and from school and to other functions as authorized by the boards of education, or the boards may, at their discretion, purchase such buses and equipment through whatever system of centralized purchasing is established by the state department of education for such purpose, provided that state subsidy payments shall be based on the amount of the lowest price available to the boards by either method of purchase. No such board of education shall be deprived of any form of state assistance in the purchase of said buses and equipment by reason of purchases of said buses and equipment on an individual contract. Boards of education, in the purchase of said buses and equipment on individual contract shall make such purchases on the following terms:

(A) Not less than one-fourth of the purchase price thereof shall be paid in cash.

(B) Not less than an additional one-fourth of the purchase price thereof shall be paid within one year from the date of purchase.

(C) Not less than an additional one-fourth of the purchase price thereof shall be paid within two years from the date of purchase.

(D) The remaining balance of the purchase price thereof shall be paid within three years for the date of purchase. Such boards may issue the notes of the school districts signed by the president and the clerk of the board, and specifying the terms of the purchase including deferred payments as provided in this section, which notes may bear interest at a rate not exceeding four per cent per annum. In the legislation under which such notes are authorized, the board shall make provision for levying and collecting annually by taxation amounts sufficient to pay the interest and the specified portion of the principal. Revenues derived from local taxes or otherwise, for the purpose of providing transportation of children or for defraying the current operating expenses of such district, may be applied to the payment of such interest and the retirement of such notes.

The purchase of school buses shall be made only after competitive bidding in accordance with divisions (A), (B), (C), (D), (E), (F), (H), and (I) of section 3313.46 of the Revised Code. Separate and independent bids shall be received with respect to the chassis and body type, and shall state that the buses, when assembled and prior to delivery, comply with the safety regulations of the department of education adopted by and with the advice and consent of the director of highway safety pursuant to section 4511.76 of the Revised Code and all other pertinent provisions of law. (131 v H 760. Effective 11-8-65)

20384

INSURANCE ON BUSES AND PUPILS

3327.09

The board of education of each school district may procure liability and property damage insurance covering each school bus or motor van and accident insurance covering all pupils transported under the authority of such board. This insurance shall be procured from a recognized insurance company authorized to do business of this character in the state, and such accident insurance shall provide compensation for injury or death to any pupil caused by an accident arising out of or in connection with the operation of such school bus, motor van, or other vehicle used in the transportation of school children, in such amounts and upon such terms as may be agreed upon by the board and the insurance company. The amount of liability insurance carried on account of any school bus or motor van shall not exceed five hundred thousand dollars. Such insurance coverage may be effected in one or more recognized insurance companies authorized to do business in this state. (130 v H 268. Effective 9-16-63)

QUALIFICATION OF DRIVER

3327.10

(A) No person shall be employed as driver of a school bus or motor van, owned and operated by any school district or privately owned and operated under contract with any school district in this state, who has not received a certificate from the county board of education of the county in which he is to be employed, in case such person is employed by a school district under the supervision of the county board, or by the superintendent of schools, in case such person is employed by the board of a city or exempted village school district, certifying that such person is at least twenty-one years of age and is of good moral character and is qualified physically and otherwise for such position. The county board or the superintendent, as the case may be, shall provide for an annual physical examination that conforms with regulations adopted by the state board of education of each driver to ascertain his physical fitness for such employment. Any certificate may be revoked by the authority granting the same on proof that the holder has been guilty of improper conduct, failing to file all traffic convictions with the county board or the superintendent, or neglect of duty and the said driver's contract shall be thereby terminated and rendered void.

(B) No person shall be employed as driver of a school bus or motor van not subject to the regulations of the department of education pursuant to division (A) of this section who has not received a certificate from the school administrator or contractor certifying that such person is at least twenty-one years of age, is of good moral character, and is qualified physically and otherwise for such position. Each driver shall have an annual physical examination which conforms to the state highway patrol regulations, ascertaining his physical fitness for such employment. Any certificate may be revoked by the authority granting the same on proof that the holder has been guilty of improper conduct, failing to file all traffic convictions with the school administrator or contractor, or neglect of duty and such driver's contract shall be thereby terminated and rendered void.

20885

(C) Any person who drives a school bus or motor van must give satisfactory and sufficient bond except a driver who is an employee of a school district and who drives a bus or motor van owned by the school district. (130 v H 161. Effective 10-14-63. 129 v 1003)

MAINTENANCE OF SCHOOL BUS TURN-AROUND POINTS

3327.12

The board of education of a city, exempted village, or local school district may maintain school bus turn-around points. At the request of such a board, a municipal corporation may maintain turn-around points on municipal roads; the township trustees may maintain turn-around points on township roads; and the county commissioners may maintain turn-around points on county roads.

The municipal corporation, township trustees, or county commissioners may also, at the request of a board of education, maintain turn-around points located on private property after an investigation by such board of education has determined that such maintenance is necessary for the use of such private property as a turn-around point for school buses. Such board of education may provide the cost of the materials utilized for any such maintenance. (131 v H 782. Effective 11-5-65)

Section 4503.17

(A) No school bus as defined in division (E) of section 4511.01 of the Revised Code is required to pay the annual license tax provided for in section 4503.02 of the Revised Code or to apply for or display registration plates, provided: the school bus complies with the requirements of sections 4511.76 to 4511.77, inclusive, of the Revised Code.

(B) The owner of a school bus, other than a board of education, which is used as a school bus during the school year under a contract with a board of education may, upon proper application for registration and the payment of a license fee of twenty-five dollars, use such bus during summer vacation periods to transport children and their authorized supervisors to and from any camping function sponsored by a nonprofit tax-exempt, charitable, or philanthropic organization. The application for registration of such bus shall be accompanied by:

(1) An affidavit, prescribed by the registrar of motor vehicles and signed by the owner of such bus, stating that such bus is to be used exclusively, during the summer months, to transport school children to and from any school function or to transport children and their authorized supervisors to and from any camping function sponsored by a nonprofit, tax-exempt, charitable, or philanthropic organization;

(2) A certificate from the state highway patrol stating that such bus is safe for operation in accordance with such standards as are prescribed by the state highway patrol.

20886

TRAFFIC LAWS--OPERATION OF MOTOR VEHICLES

Section 4511.01

Definitions

(E) "School bus" means every bus designed for carrying more than nine passengers which is owned by a public, private, or governmental agency or institution of learning and operated for the transportation of children to or from a school session or a school function, or owned by a private person and operated for compensation for the transportation of children to or from a school session or a school function; provided "school bus" does not include a bus operated by a municipally owned transportation system, a mass transit company operating exclusively within the territorial limits of a municipal corporation, nor a common passenger carrier certified by the public utilities commission unless such bus is devoted exclusively to the transportation of children to and from a school session or a school function.

LOCAL TRAFFIC REGULATIONS

Section 4511.07

Sections 4511.01 to 4511.78, inclusive, 4511.99 and 4513.01 to 4513.37, inclusive, of the Revised Code do not prevent local authorities from carrying out the following activities with respect to streets and highways under their jurisdiction and within the reasonable exercise of the police power:

(J) Regulating traffic in reference to school buses.

No ordinance or regulation enacted under divisions (D), (E), (F), (G), (I), or (J) of this section shall be effective until signs giving notice of such local traffic regulations are posted upon or at the entrance to the highway or part thereof affected, as may be most appropriate.

VEHICLES REQUIRED TO STOP AT GRADE CROSSINGS

Section 4511.63

The operator of any motor vehicle or trackless trolley, carrying passengers, for hire or of any school bus, or of any vehicle carrying explosives or flammable liquids as a cargo, or such part of a cargo as to constitute a hazard, before crossing at grade any track of a railroad, shall stop such vehicle or trackless trolley, and while so stopped he shall listen through an open door or open window and look in both directions along the track for any approaching train, and for signals indicating the approach of a train, and shall proceed only upon exercising due care after stopping, looking and listening as required by this section and upon proceeding, the operator of any such vehicle shall cross only in such gear of the vehicle that there will be no necessity for changing gears while traversing such crossing and the operator shall not shift gears while crossing the tracks.

This section does not apply at street railway grade crossings within a municipal corporation, or to abandoned tracks, spur tracks, side tracks, and industrial tracks when the public utilities commission has authorized and approved the crossing of such tracks without making the stop required by this section.

SCHOOL BUSES

Regulations Concerning School Buses

Section 4511.75

(A) The driver of a vehicle upon a highway outside the limits of a municipal corporation, upon meeting or overtaking from either direction any school bus which has stopped on the highway for the purpose of receiving or discharging any school child, shall stop the vehicle not less than ten feet from such school bus and shall not proceed until such school bus resumes motion, or until signaled by the driver to proceed.

(B) Where a highway has been divided into two roadways as set forth in section 4511.35 of the Revised Code a driver of a vehicle proceeding on one roadway of said highway need not stop when approaching a school bus which has stopped on the other roadway of said highway for the purpose of receiving or discharging any school child. The driver of any vehicle proceeding on the same roadway of said highway as the school bus shall comply with division (A) of this section.

(C) School buses operating on divided highways or on highways with four or more traffic lanes shall receive and discharge all school children on their residence side of the highway.

(D) No school bus driver shall start his bus until after any child who may have alighted therefrom has reached a place of safety on his residence side of the road.

REGULATIONS FOR OPERATION OF SCHOOL BUSES

Section 4511.76

(A) The department of education by and with the advice and consent of the director of highway safety shall adopt and enforce regulations relating to the construction, design, equipment, and operation of all school buses owned and operated by any school district or privately owned and operated under contract with any school district in this state. When such buses are privately owned and operated under contract with any school district in this state, these regulations shall, by reference, be made a part of any such contract with a school district. Every school district, its officers and employees, and every person employed under contract by a school district shall be subject to such regulations.

20888

Any officer or employee of any school district who violates any such regulation, or who fails to comply with regulations in any contract executed by him on behalf of a school district, is guilty of misconduct and subject to removal from office or employment. Any person operating a school bus under contract with a school district who fails to comply with any such regulation is guilty of a breach of contract, and such contract shall be canceled by the responsible officers of such school district.

No person shall operate such a school bus within this state in violation of the regulations of the department of education. No person, being the owner thereof or having the supervisory responsibility therefor, shall permit the operation of such a school bus within this state in violation of the regulations of the department of education.

(B) The department of highway safety shall adopt and enforce such regulations as relate to the safety of the construction, design, equipment, and operation of all school buses not subject to the regulations of the department of education pursuant to division (A) of this section. Such regulations shall be adopted pursuant to the provisions of Chapter 119. of the Revised Code.

No person shall operate such a school bus within this state in violation of the regulations of the department of highway safety. No person, being the owner thereof or having the supervisory responsibility therefor, shall permit the operation of such a school bus within this state in violation of the regulations of the department of highway safety.

(C) The department of highway safety shall adopt and enforce such regulations as relate to the issuance of a license under section 4511.763 of the Revised Code. Such regulations may relate to the moral character of the applicant; the condition of the equipment to be operated; the liability and property damage insurance carried by the applicant; the posting of satisfactory and sufficient bond; and such other rules and regulations as the director of highway safety shall deem reasonably necessary for the safety of the pupils to be transported.

SCHOOL BUS INSPECTION

Section 4511.761

The state highway patrol shall inspect every school bus to ascertain whether its construction, design, and equipment comply with the regulations adopted pursuant to section 4511.76 of the Revised Code and all other provisions of law.

The superintendent of the state highway patrol shall adopt a distinctive inspection decal not less than twelve inches in size, and bearing the date of the inspection, which shall be affixed to the outside surface of each side of each school bus which upon such inspection is found to comply with the regulations adopted pursuant to section 4511.76 of the Revised Code. The appearance of said decal shall be changed from year to year as to shape and color in order to provide easy visual inspection.

20889

No person shall operate, nor shall any person being the owner thereof or having supervisory responsibility therefor permit the operation of, a school bus within this state unless there is displayed thereon the decals issued by the state highway patrol bearing a date of inspection prior to the fifteenth day of October in the calendar year in which the decals were issued, except for a bus licensed by the department of highway safety pursuant to section 4511.763 of the Revised Code which shall display decals bearing a date of inspection between the sixteenth day of July and the first day of September of the calendar year in which the inspection was made, but if a bus is purchased after the first day of September, it shall display decals bearing a date of inspection later than the date the bus is purchased and prior to the date of its use for the transportation of pupils.

LICENSING

Section 4511.763

No person, partnership, association, or corporation shall engage in the transportation of pupils to or from school, for profit, or enter into a contract with a board of education of any school district, without being licensed by the department of highway safety.

REGISTRATION OF SCHOOL BUSES

Section 4511.764

The superintendent of the state highway patrol shall require school buses, as defined in division (E) of section 4511.01 of the Revised Code, to be registered, in the name of the owner, with the state highway patrol on forms and in accordance with regulations as the superintendent may adopt.

When the superintendent is satisfied that the registration has been completed, he shall assign an identifying number to each school bus registered in accordance with this section. The number so assigned shall be marked on the front and rear of the vehicle in black lettering not less than six inches in height and will remain unchanged as long as the ownership of that vehicle remains the same.

No person shall operate, nor shall any person, being the owner thereof or having supervisory responsibility therefor, permit the operation of a school bus within this state unless there is displayed thereon an identifying number in accordance with this section.

20890

Section 4513.17 (C and D)

Flashing lights are prohibited on motor vehicles, except as a means for indicating a right or a left turn, or in the presence of a vehicular traffic hazard requiring unusual care in approaching, or overtaking or passing. This prohibition does not apply to the use of flashing, oscillating, or rotating amber light on emergency vehicles, *** road service vehicles servicing or towing a disabled vehicle, traffic line stripers, snow plows, rural mail delivery vehicles, state highway survey vehicles, funeral escort vehicles, and similar equipment operated by the department or local authorities, nor to vehicles or machinery permitted by section 4513.11 of the Revised Code to have a flashing red light.

Except a person operating a public safety vehicle, as defined in division (E) of section 4511.01 of the Revised Code, or a school bus, no person shall operate or move upon any public street or highway any vehicle or equipment which has a flashing red or a flashing combination red and white light, or any vehicle or equipment which has an oscillating or rotating red light or a combination red and white oscillating or rotating light. This section shall not prohibit the use of warning lights required by law or the simultaneous flashing of turn signals on disabled vehicles.

DISPLAY OF WARNING DEVICES ON DISABLED VEHICLES

Section 4513.28

(A) Whenever any motor truck, trackless trolley, bus, commercial tractor, trailer, semi-trailer, or pole trailer is disabled upon the traveled portion of any highway or the shoulder thereof outside of any municipality, or upon any freeway, expressway, thruway, and connecting, entering or existing ramps within a municipality, at any time when lighted lamps are required on vehicles and trackless trolleys, the operator of such vehicle or trackless trolley shall display the following warning devices upon the highway during the time the vehicle or trackless trolley is so disabled on the highway except as provided in division (B) of this section:

(1) A lighted fusee shall be immediately placed on the roadway at the traffic side of such vehicle or trackless trolley, unless red electric lanterns or red reflectors are displayed.

(2) Within the burning period of the fusee and as promptly as possible, three lighted flares or pot torches, or three red reflectors or three red electric lanterns shall be placed on the roadway as follows:

(a) One at a distance of forty paces or approximately one hundred feet in advance of the vehicle;
(b) One at a distance of forty paces or approximately one hundred feet to the rear of the vehicle or trackless trolley except as provided in this section, each in the center of the lane of traffic occupied by the disabled vehicle or trackless trolley;
(c) One at the traffic side of the vehicle or trackless trolley.

20891

(B) Whenever any vehicle used in transporting flammable liquids in bulk, or in transporting compressed flammable gases, is disabled upon a highway at any time or place mentioned in division (A) of this section, the driver of such vehicle shall display upon the roadway the following warning devices:

(1) One red electric lantern or one red reflector shall be immediately placed on the roadway at the traffic side of the vehicle;

(2) Two other red electric lanterns or two other red reflectors shall be placed to the front and rear of the vehicle in the same manner prescribed for flares in division (A) of this section.

(C) When a vehicle of a type specified in division (B) of this section is disabled, the use of flares, fusees, or any signal produced by flames as warning signals is prohibited.

(D) Whenever any vehicle or trackless trolley of a type referred to in this section is disabled upon the traveled portion of a highway or the shoulder thereof, outside of any municipality, or upon any freeway, expressway, thruway and connecting, entering or exiting ramps within a municipality, at any time when the display of fusees, flares, red reflectors, or electric lanterns is not required, the operator of such vehicle or trackless trolley shall display two red flags upon the roadway in the lane of traffic occupied by the disabled vehicle or trackless trolley, one at a distance of forty paces or approximately one hundred feet in advance of the vehicle or trackless trolley, and one at a distance of forty paces or approximately one hundred feet, to the rear of the vehicle or trackless trolley, except as provided in this section.

(E) The flares, fusees, lanterns, red reflectors, and flags to be displayed as required in this section shall conform with the requirements of section 4513.27 of the Revised Code applicable thereto.

(F) In the event the vehicle or trackless trolley is disabled near a curve, crest of a hill, or other obstruction of view, the flare, flag, reflector, or lantern in that direction shall be placed as to afford ample warning ot other users of the highway, but in no case shall it be placed less than forty paces or approximately one hundred feet nor more than one hundred twenty paces or approximately three hundred feet from the disabled vehicle or trackless trolley. (130 H. 603)

UNIT III

DIGEST OF

MOTOR VEHICLE TRAFFIC LAWS

OF OHIO

38/39 20893

STATE OF OHIO
JAMES A. RHODES
Governor

DEPARTMENT OF HIGHWAY SAFETY
WARREN C. NELSON
Director

BUREAU OF MOTOR VEHICLES
FRED RICE, Registrar

STATE HIGHWAY PATROL
R. M. CHIARAMONTE, Supt.

Digest of MOTOR VEHICLE LAWS OF OHIO

(REVISED SEPTEMBER 1969)

IMPORTANT: Your driver's license expires on your birthday, in the year indicated on the license!

40/41 20394

Dear Ohioan:

Good highways are necessary to transport Ohio-made products to the market to provide more and better jobs for Ohioans. Ohio is the transportation center of the nation. Our highways are the finest. As you drive on our fine highways you share with more than six million drivers the responsibility of being a safe and courteous driver.

By knowing and understanding the enclosed regulations and by being a cautious and careful driver you can help make Ohio highways the safest in the nation. Wear your safety belt at all times.

My very best wishes for a safe, accident-free driving record.

Sincerely,

James A. Rhodes

JAMES A. RHODES
Governor of Ohio

20885

PRE-EXAMINATION

For the purpose of obtaining an Ohio Temporary Instruction Permit all persons are required to contact a driver license examination station and undergo a pre-examination. This examination consists of a vision test, a test of the applicant's knowledge of motor vehicle laws, and a sign test. Every applicant will be required to present evidence of correct date of birth either by a birth certificate or other legal documentary evidence. If under 18, applicant must first submit satisfactory evidence, by presentation of an official certificate, of having successfully completed a driver education course approved by the State Department of Education—or a driver training course approved by the Director of Highway Safety.

APPOINTMENTS FOR DRIVER EXAMINATIONS

All driver license examinations are conducted by the State Highway Patrol and consist of the following: (1) A test of your knowledge of the laws and rules for safe driving. (2) A test of your vision. (3) A test of your knowledge and understanding of road signs and traffic signals. (4) A test of your driving and parallel parking ability—and observance of regulating signals, signs and road markings.

Driver examinations are given by appointment only, in order to reduce the amount of time the prospective examinee must spend at the examining station. When an appointment to undergo a driver examination has been made, the prospective examinee must be punctual; and if it is found that due to unforeseen circumstances he is unable to appear at the appointed time, he shall notify the examination station or the Highway Patrol where the appointment was made. Please cancel appointments far enough in advance so that another examination time may be assigned.

A careful study of the following information will help you pass the examination and will improve your knowledge of the laws, road rules, signs and signals. No road examination will be permitted in an unsafe vehicle.

NOTE: Before and during the actual driving test follow the examiner's instructions. At no time will you be instructed to operate your motor vehicle in violation of any law or safe driving regulation.

EXEMPTIONS FROM EXAMINATIONS

TAXI CAB DRIVER who has a currently effective operator's license is exempt from a chauffeur's examination.

MILITARY OR NAVAL SERVICE PERSONNEL ON ACTIVE DUTY, and in possession of a driver's permit, when operating an official motor vehicle, in connection with such duty, is exempt from license requirements of this state. Also—when on furlough during period of active duty, and for 6 months after such duty—provided he had an active license prior to active duty.

Registrar may waive operator's or chauffeur's examination of any honorably discharged military or naval personnel, and without any mental or physical disability that would affect such driving—providing (a) he had an active license in this state at the time he commenced such service and (b) such application is made not more than 6 months following discharge.

MINIMUM AGE

The minimum age for a Temporary Permit or Operator License is 16 years. The application for a Temporary Permit or Operator's License of a person under 18 years of age must be signed by either parent, guardian or other person having custody—or when neither exists, by a responsible person who is at least 21 years of age.

Any negligence or willful or wanton misconduct of a minor under 18, when driving a motor vehicle upon a highway, shall be imputed to the person who has signed the application of such minor. Such person(s) shall be jointly and severally

43 20336

liable with such minor for any damages caused by such negligence or willful or wanton misconduct.

TEMPORARY INSTRUCTION PERMIT

An applicant must undergo and pass a pre-examination before he is permitted to obtain a temporary instruction permit. For details contact the nearest State Driver License Examining Station. Such temporary instruction permit, when granted and in the applicant's immediate possession entitles him to drive a motor vehicle upon any street or highway—and only when accompanied by a licensed operator or chauffeur, who is actually occupying a seat beside the driver. The permit is valid for a six-month period from date of issuance.

OUT-OF-STATE LICENSES

Any person having in his possession a valid out-of-state license recognized by the State of Ohio, is exempt from obtaining a Temporary Instruction Permit, but shall submit to the regular examination in obtaining an operator's or chauffeur's license in this state.

No person shall receive an operator's or chauffeur's license, or a motorcycle operator's endorsement of an operator's or chauffeur's license, unless and until he surrenders to the Registrar all valid licenses in his possession issued to him by another jurisdiction recognized by this state. All surrendered licenses shall be returned by the Registrar to the issuing authority, together with information that a license is now issued in this state. No person shall be permitted to have in his possession more than one valid license at any time. The Registrar may promulgate and enforce rules governing the use of such instruction permit.

PROBATIONARY LICENSE

A Probationary License shall be issued to persons between the ages of 16 and 21 years. The Registrar of Motor Vehicles shall revoke the Probationary License issued to any person—when such person (before reaching his 18th birthday) has been convicted, pleaded guilty, or adjudged in juvenile court, of having committed a total of three separate motor vehicle violations.

RESTRICTED LICENSE

The Registrar of Motor Vehicles—upon issuing an operator's or chauffeur's license, a motorcycle operator's endorsement, an operator's or chauffeur's license renewal, or the renewal of any other license issued under Chapter 4507. of the Revised Code—may, whenever good cause appears, impose restrictions suitable to the licensee's driving ability with respect to the type of or special mechanical control devices required on a motor vehicle, which the licensee may operate; or such other restrictions applicable to the licensee as the Registrar determines to be necessary.

Physical Disabilities

Persons who have physical disabilities; or those who must have attachments either to their person or on their motor vehicles—must have a Restricted Temporary Instruction Permit. Such permits are issued only after a pre-examination has been conducted, the disability determined, and attachments necessary for safe operation required. This may include persons who are of short stature and who need special equipment for driving.

CHAUFFEUR'S LICENSE

1. The Minimum age for a chauffeur's license is 18 years.
2. A chauffeur's license issued after an examination has been passed is valid for a period of three years from the last birthday, before such chauffeur license is issued.

2065

3. Chauffeur's licenses being renewed are valid for a period of three years from date of expiring chauffeur's license.
4. A 2-1/2" x 2-1/2" photograph is required. The picture must have been taken within thirty days of the time of the application for a chauffeur's license.
5. A valid operator's license may be converted to a chauffeur's license. The operator must take a complete driver examination including a special chauffeur's test.

MOTORCYCLES AND MOTORCYCLISTS

1. Motorcycle operators must have a special license. If the cyclist has no automobile driver's license, he must obtain a restricted motorcycle license costing $4.00 for four years. If he has an auto driver's license, his motorcycle permit may be added as an endorsement to it, also at a cost of $4.00 for four years.
2. The new law prohibits handlebars or grips more than 15 inches higher than the saddle; requires that both operators and passengers wear helmets and eye protectors approved by the director of highway safety; and demands that all motorcycles be equipped with rear-view mirrors and effective mufflers containing baffle plates.
3. Devices for producing excessive smoke or gas, and any equipment which permits oil or any other chemical to flow upon the exhaust pipe or muffler, are prohibited, as are muffler cutouts or by-passes which allow excessive noise.
4. Applicants for motorcycle operator licenses must give an actual demonstration of their ability to exercise ordinary and reasonable control in the operation of the cycle by driving it under the supervision of an examining officer. They must also pass tests on physical condition, understanding of traffic control devices, and knowledge of motor vehicle laws.
5. Motorcycles and bicycles are subject to the same rules and regulations as motor vehicles, in so far as practicable.
6. Every person riding a motorcycle or bicycle upon a roadway shall be governed by the same regulations—as if he were driving any vehicle. Every operator of a motor bike, motor scooter, motorcycle, or similar vehicle must be properly licensed under the Ohio Driver's License Law.
7. No motorcycle or bicycle shall be used to carry more persons at one time than the number for which it is designed and equipped.

YOUR LICENSE: A TRUST AND A FAITH

No person shall:

1. Display, or cause or permit to be displayed, or possess any operator's or chauffeur's license or temporary permit, knowing the same to be fictitious, or to have been canceled, revoked, suspended, or altered.
2. Lend to a person not entitled thereto, or knowlingly permit him to use any operator's or chauffeur's license or temporary permit, not issued to the person so displaying the same.
3. Display, or represent as one's own, any operator's or chauffeur's license or temporary permit, not issued to the person so displaying the same.
4. Fail to surrender to the Registrar of Motor Vehicles, upon his demand, any operator's or chauffeur's license or temporary permit, which has been suspended, canceled, or revoked.
5. Use a false or fictitious name, or give a false or fictitious address, in any application for an operator's or chauffeur's license or temporary permit.

It is unlawful to permit your car to be operated by:

1. A person who does not have a driver's license.
2. By the holder of a Temporary Instruction Permit when not accompanied by a licensed driver on the seat beside him.

45 20338

DRIVER LICENSE SUSPENSIONS

The trial judge of any court of record . . . . in addition to suspensions or revocations of licenses for periods of time not exceeding three years, and in addition to, or independent of, all other penalties provided by law or by ordinance . . . . shall impose a suspended jail sentence not to exceed six months, providing that imprisonment was not imposed for the offense for which the person was convicted.

No court shall suspend the first thirty days of suspension of license provided for under this section.

The violations for which a driver's license may be revoked or suspended are:

(A) Homicide by vehicle;

(B) Operating a motor vehicle while under the influence of intoxicating liquor or narcotic drug;

(C) Perjury or the making of a false affidavit, under Sections 4507.01 to 4507.39, inclusive, of the Revised Code, or any other law of this state, requiring the registration of motor vehicles, or regulating their operation on the highway.

(D) Any crime punishable as a felony under the motor vehicle laws of this state or any other felony in the commission of which a motor vehicle is used;

(E) Failing to stop and disclose identity at the scene of the accident when required by law to do so;

(F) Drag racing as defined in division (A) of Section 4511.25 of the Revised Code;

(G) Willfully eluding or fleeing a police officer.

Ohio's Point System Law

Within ten days after conviction or bond forfeiture of a person in a mayor's court or a court of record for any violation under the revised uniform traffic code, Section 4511.01 to 4511.78, inclusive, 4511.99 and 4513.01 to 4513.36, inclusive, or of any law or ordinance regulating the operation of vehicles, street cars, and trackless trolleys on highways, said court shall prepare and forward to the Bureau of Motor Vehicles abstracts of court records covering such conviction or bond forfeiture.

The Registrar, within ten days after receipt of such abstract, shall record the date of conviction or bond forfeiture and the number of points for each conviction or bond forfeiture based on the following formula:

(1) Violation of section 4507.38 or 4507.39 of the Revised Code or any ordinance prohibiting the operation of a motor vehicle while the operator's license is under suspension or revocation ..... **6 points**

(2) Violation of section 4549.04 of the Revised Code or any ordinance prohibiting the operation of a motor vehicle without consent of the owner .. **6 points**

(3) Homicide by vehicle ..... **6 points**

(4) Violation of section 4511.19 of the Revised Code or any ordinance prohibiting the operation of a motor vehicle while under the influence of alcohol or drugs ..... **6 points**

(5) Violation of section 4549.02 of the Revised Code or any ordinance requiring the driver of a vehicle to stop and disclose identity at the scene of an accident ..... **6 points**

(6) Violation of section 4511.02 of the Revised Code or any ordinance prohibiting the willful fleeing or eluding of a police officer ..... **6 points**

(6)

20899

(7) Any crime punishable as a felony under the motor vehicle laws of this state, or any other felony in the commission of which a motor vehicle was used ..... 6 points

(8) Operating a motor vehicle in violation of a restriction imposed by the registrar ..... 2 points

(9) Violation of section 4511.251 of the Revised Code or any ordinance prohibiting drag racing ..... 6 points

(10) Violation of section 4511.20 of the Revised Code or any ordinance prohibiting the reckless operation of a motor vehicle ..... 4 points

(11) Violation of any law or ordinance pertaining to speed ..... 2 points

(12) All other moving violations pertaining to the operation of motor vehicles reported under this section except any violations under section 5577.01 to 5577.99, inclusive, of the Revised Code ..... 2 points

Whenever the points charged against any person exceed five, the Registrar shall forward to such person a warning letter, listing the reported violations.

When any person has more than seven points charged against him, he shall be required to submit to a driver license examination or a physical examination, or both.

When the number of points against any person reaches 12 within a two-year period, the Registrar shall, advise the subject that his license will be suspended for a period of time, depending upon the number of prior suspensions under this statute—effective on the 20th day after the mailing of the suspension notice.

Exceptions:

Unless the licensee files a petition in the municipal court or county court—or in case the person is under the age of eighteen years, to the juvenile court—in the county where such person resides, agreeing to pay the costs of the proceedings and alleging that the licensee can show cause why his license should not be suspended. The court shall decide such issue as to whether the person is a habitual traffic law violator. If the court finds from the evidence submitted that he is a habitual traffic law violator, then the court may:

1. Uphold the suspension made by the Registrar.
2. Withhold the suspension, or a part thereof, and provide such conditions or probations as the court deems proper.

Any person whose license or permit or privilege to operate a motor vehicle has been suspended under this section, and who, during such suspension drives any motor vehicle, shall be fined not more than $500, or imprisoned not less than three days nor more than six months—and no court shall suspend the first three days of any sentence provided under this section.

SPEED RESTRICTIONS

Speed Limits

Automobiles may not be operated upon streets or highways at a speed either greater or less than is reasonable and proper, having due regard for the traffic, surface and width of the street or highway and of any other conditions then existing. A driver must keep his vehicle under such control as to be able to bring it to a stop within the assured clear distance ahead.

It shall be unlawful to drive at a speed exceeding:

(1) 15 miles per hour in all alleys within a municipal corporation.

47 20900

(2) **20 miles per hour** when passing a school building or the grounds thereof during school recess and while children are going to or leaving school during the opening or closing hours. Also when appropriate signs giving notice of the existence of the school are erected—except, that on controlled-access highways and expressways, if the right-of-way line fence has been erected without pedestrian opening, the speed shall be governed by provision in paragraph (5) below. On freeways, if the right-of-way line fence has been erected without pedestrian opening, the speed shall be governed by provisions in paragraphs (8) and (9) below.

(3) **25 miles per hour** in all other portions of a municipal corporation, except on state routes, through highways outside business districts, and alleys.

(4) **35 miles per hour** on all state routes or through highways (which are not controlled-access highways) within municipal corporations outside business districts, except as provided in paragraphs (5) and (6) below.

(5) **50 miles per hour** on controlled-access highways and expressways within municipal corporations.

(6) **50 miles per hour** also on state routes within municipal corporations outside urban districts, unless a lower prima-facie speed is established.

(7) **60 miles per hour** during the daytime and **50 miles per hour during the nighttime** on highways outside of municipal corporations—**except** 50 miles per hour at all times . . . for operators of trucks and commercial tractors, which weigh in excess of 4000 pounds empty weight; also for school buses, street cars and trackless trolleys.

(8) **60 miles per hour at all times on freeways with paved shoulders inside municipal corporations**—**except** 50 miles per hour at all times for operators of trucks and commercial tractors weighing in excess of 4000 pounds empty weight, as well as school buses.

(9) **70 miles per hour at all times on freeways outside municipal corporations**—**except** 55 miles per hour for operators of trucks and commercial tractors weighing in excess of 4000 pounds, as well as school buses.

The State Director of Highways may set up or permit local authorities to set up speed zones of greater or lesser speed than these prima-facie speed limitations upon the basis of engineering and traffic investigations. Such studies must show that the prima-facie speed is greater or lesser than is reasonable or safe under the conditions found to exist at the locations to be designated as special speed zones. The greater or lesser speed, whichever is determined, shall be effective only when appropriate signs giving notice thereof are erected at these special speed zones.

Racing on Public Roads

No person shall participate in a drag race on a public road. A drag race is one which consists of operation of two or more vehicles from a point, side by side and at accelerating speeds in a competitive attempt to out-distance each other. Or the operation of one or more vehicles over a common selected course, from the same point to the same point, when timing is made of the participating vehicles involving competitive accelerations of speeds. Persons rendering assistance in any manner to such competitive use of vehicles shall be equally charged as the participants.

Speed Limits on Bridges

No person shall drive a motor vehicle over any bridge or other elevated structure, constituting a part of a highway, at a speed which is greater than the maximum speed that can be maintained with safety to such bridge or structure, when such structure is sign-posted.

Minimum Speed Limits

No person shall operate a vehicle at such a slow speed as to impede or block the normal and reasonable movement of traffic, except when reduced speed is necessary for safe operation or to comply with law.

Whenever the Director of Highways or local authorities determine, on the basis of an engineering and traffic investigation, that slow speeds on any part of a controlled-access highway consistently impede the normal and reasonable movement of traffic—the Director of Highways or such local authority may declare a minimum speed limit, below which no person shall operate a motor vehicle, except when necessary for safe operation or in compliance with law. (**No minimum speed limit established hereunder shall be less than 30 miles per hour**; nor effective until provisions relating to appropriate signs have been fulfilled and local authorities have obtained the approval of the Director of Highways.)

Speed Clocked By Radar—Arrest Without Warrant

A driver, who has been detected speeding by radar, or by any electrical timing device, may be arrested until a warrant can be obtained for such arrest. (Posted radar or other similar warning signs no longer required.)

SAFE DRIVING PRACTICES

When being overtaken and passed by another motor vehicle approaching from the rear you shall not increase your speed until completely passed by the overtaking vehicle.

When overtaking and passing another vehicle on a two lane highway, make certain of assured clear distance ahead, give audible signal to the vehicle to be overtaken, pass to left at safe distance, and be sure not to 'cut-in' too closely ahead of the overtaken vehicle.

The purpose of highways and streets being marked in lanes for traffic proceeding in the same direction is:

1. When the roadway is sufficiently wide to permit more than one line of traffic, lanes are marked to clearly divide the lines of traffic to more safely facilitate the flow. Slow traffic should travel in the extreme right lane.
2. To provide marked lanes for passing and other safety measures as required.

Whenever any roadway has been divided into three or more clearly-marked lanes, or wherever, within a municipal corporation traffic is lawfully moving in two or more substantially continuous lines in the same direction—a vehicle shall be driven, as nearly as practicable, entirely within a single lane or line of traffic—and shall not move therefrom until the driver has first made certain that such movement can be made with safety.

When entering a through highway you must yield the right-of-way to all vehicles on said through highway.

When making a left turn you must yield right-of-way to all vehicles approaching from the opposite direction.

When parked at a curb, the most important thing is to make certain the portion of the highway you are about to enter is free from oncoming traffic for a distance sufficient to allow you to safely enter that part of the roadway.

The meaning of the yellow line on the highway is: When the yellow line is in your lane do not pass. When there are double yellow lines, passing in either direction is prohibited.

ENTERING OR LEAVING A VEHICLE

Get into a vehicle from the curb side, when it is parked parallel at the curb of any street or highway, where there is even a small amount of traffic. Getting either into or out of a vehicle on the roadway side may cause sudden stops or collisions in the passing traffic.

20302

LIGHTS AND REQUIREMENTS

The minimum number of lights required on a motor vehicle operated at night are — Two head lights, one red tail light and white light so arranged as to illuminate the rear license plate.

1. The law requires you to dim your lights upon the approach of an oncoming vehicle.
2. Only one spot light is permitted on a vehicle and the beam must be directed to the right on the left side of the vehicle and not to exceed one hundred feet ahead.
3. Every vehicle must display headlights and tail light from one-half hour after sunset to one-half hour before sunrise, and at any other time when there is not sufficient natural light to render discernible persons, vehicles, and substantial objects on the highway.

When following a vehicle at night you should lower the beam of your light so as not to blind the driver ahead.

A driver's reaction to red flags, flares and fusees on a highway should be: Danger ahead — slow down and stop.

HIGH BEAM

TO BE USED IN OPEN COUNTRY EXCEPT WHEN APPROACHING ONCOMING CAR.

LOW BEAM

TO BE USED ON LIGHTED STREETS, WHEN FOLLOWING OTHER CAR, DRIVING IN FOG AND APPROACHING ONCOMING CAR.

PARALLEL PARKING TEST

This test is very important as it tests the applicant's judgment and ability to handle a motor vehicle. It is a known fact that a driver who can park will eliminate traffic congestion and accidents.

The following procedure should be used in parallel parking:

1. Stop even with and about a foot away from the car in front of the space where you are going to park.
2. Make sure that you will not interfere with oncoming traffic.
3. Turn steering wheel sharply right and back slowly towards the curb.
4. When your front wheels are opposite the rear bumper of the car ahead, quickly turn steering wheel to extreme left and back slowly to car behind.
5. Straighten out front wheels and pull into final parking position a few inches from curb allowing adequate clearance at both ends of car.
6. The test is presumed to be successfully completed when the driver has properly removed his car from within the parking zone.

20903

FIRST, and of greatest importance, remember that traffic may be approaching from the rear.

Step 1. Always look back and make sure that the road is clear, before even attempting to park.

PARKING

It is illegal to park upon the paved or main traveled part of a highway outside of a business or residence district.

Six places where it is illegal to park a motor vehicle.

1. In front of a public or private driveway.
2. Within ten feet of a fire hydrant.
3. Within twenty feet of a cross-walk at any intersection.
4. Within thirty feet upon the approach to any stop sign.
5. Alongside any vehicle stopping or parked at the edge or curb of a street.
6. Within one foot of another parked vehicle.

The law requires a rear vision mirror. If operator is deaf, two rear vision mirrors are required—one inside and one outside.

No Passing Zones

Railroad Warning Sign

53 20906

When making right and left turns, make certain that your directional signals are operating effectively. If necessary, use hand signals as indicated. And don't forget to yield the right-of-way to traffic approaching from the opposite direction.

HAND SIGNALS

Give all signals well in advance. The following hand and arm signals control the operations of a motor vehicle.

1. Left turn — left hand and arm straight out.
2. Slowing or stopping — left hand and arm down.
3. Right turn — left hand and forearm straight up.

It is not necessary to use the hand signals if mechanical directional signals are used.

PROCEDURE FOR MAKING RIGHT & LEFT TURNS

The correct procedure in making:

1. Right turn — Give appropriate signal and stay as near to the right side of the road or curb as possible.
2. Left turn — Give appropriate signal and approach as near to the center line on your left side of the roadway as possible and leave the intersection to the right of the center of the roadway being entered.

The correct procedure for making a left turn from a roadway restricted to one-way traffic is — Give appropriate signal and approach the intersection in the extreme left hand lane entering as nearly as practicable into the left hand lane of the roadway being entered available for traffic in that direction.

RAILROAD CROSSINGS

It is unlawful to drive across a grade crossing:

1. When a crossing gate is lowered.
2. When an electrical or mechanical signal device or a human flagman gives warning of the immediate approach of a train.
3. Flashing yellow lights are sometimes used at railroad crossings, and drivers are urged to use extreme caution when observing these signals.

When a stop sign has been erected at a grade crossing all vehicles shall stop and not proceed until the driver has made certain that no train is approaching.

Note: Use caution though signals have stopped flashing — in the event another train may be approaching.

H. Soups—Continued

Essential learning (Skill and knowledge)	Scope of instruction (Suggested content)	Information (Technical and related)

	Care in cooking	Curdling: Cause Effect How to prevent Methods of serving
	Care after cooking	Storage

Suggested teaching materials: See items 8, 15, 20, 30, 108 in appendix B.

2066

SCHOOL BUS

When meeting or overtaking from either direction, a school bus which has stopped for the purpose of discharging or receiving any school child, you must stop your vehicle at least 10 feet from the school bus and not proceed until such school bus resumes motion, or until signalled by the driver to proceed.

When traveling on any highway, which has been divided into two roadways by a physical barrier or clearly indicated dividing section—so constructed to impede vehicular traffic—it shall be necessary to stop, as indicated above, but only when traveling the same direction as the school bus.

PUBLIC SAFETY AND EMERGENCY VEHICLES

On the approach of a public safety vehicle, responding to call, meaning ambulances, vehicles used by public law enforcement officers, and any vehicle used by fire departments—the driver of a motor vehicle is required to pull to the curb and remain stationary until the public safety vehicle has passed.

The driver of any vehicle other than an emergency or public safety vehicles on official business, shall not follow any emergency vehicle or public safety vehicle traveling in response to an alarm closer than 500 feet, or drive into or park such vehicle within the block where the fire apparatus has stopped in answer to a fire alarm, unless directed to do so by a police officer or a fireman.

No streetcar, trackless trolley or vehicle shall, without the consent of the fire department official in command, be driven over any unprotected hose of a fire department, when said hose is laid down on any street, private driveway or streetcar track to be used at any fire or alarm of fire.

Flashing lights are prohibited on motor vehicles, except as a means for indicating turns, or in the presence of a vehicular traffic hazard requiring unusual care in approaching, overtaking or passing. This prohibition does not apply to the use of flashing, oscillating or rotating amber lights on emergency vehicles, road service vehicles servicing or towing a disabled vehicle, traffic line stripers, snow plows, rural mail delivery vehicles, official survey vehicles and funeral escort vehicles.

Except a person operating public safety vehicles, school buses, or vehicles authorized to display slow moving vehicle emblems, no person shall operate or move upon any public street or highway any vehicle or equipment which has a flashing, oscillating, rotating red or combination red or white light.

SLOW MOVING VEHICLES

All farm machinery and other machinery which is designated for operation at a speed of 25 MPH or less shall be operated at a speed not exceeding 25 MPH, and shall display a triangular slow moving vehicle emblem (SMV). Use of the (SMV) emblem upon any other type vehicle is prohibited when such vehicle is operated at a speed of 26 MPH or more. Use of the emblem on stationary objects on the highway is also prohibited.

55 20908

STOP STREETS AND AUTOMATIC SIGNALS

You must stop before entering or crossing a highway from a private road, driveway, alley or building.

You must yield the right of way to all traffic on said highway.

When you are confronted with a 'STOP' sign or when approaching a highway from an area requiring a stop at such highway—you must come to a full stop even though no traffic is approaching and must yield the right-of-way to all vehicles not obliged to stop.

Know and obey these traffic light signals, arrows:

1. **Green alone**—move through intersection.
2. **Yellow appearing with green**—all traffic stop, except that traffic that has entered the section.
3. **Red alone**—stop.
4. **Green arrow alone**—traffic may move in direction arrow indicates. If arrow indicates a turn, right-of-way must be yielded to pedestrians.
5. **Green arrow appearing with red**—through traffic is prohibited, turn in direction indicated with caution.
6. **Signs may indicate a right turn on red**—turn may be made with caution after stopping if sign so indicates.
7. **A flashing red traffic signal is the same as a stop sign.** You must come to a full stop and only enter the intersection by yielding the right-of-way to all vehicles not required to stop at the intersection.
8. **A flashing yellow traffic signal means caution.** You must slow down and proceed through the intersection with caution.

IMPLIED CONSENT
ALCOHOL CONCENTRATION IN INTOXICATION CASES
PENALTIES

Here are the important provisions:

- Permits such persons to refuse to take such tests, but requires the Registrar, in such cases, to revoke the person's license or driving privileges for 6 months.

- Establishes procedures for advising such persons of the consequences of refusal to take the test, for revoking the license, for hearing, for review, and for notifying the Registrar of other states of cases involving persons from such states.

- Provides that a person who is dead, unconscious, or otherwise incapable of refusing such a test, is deemed not to have withdrawn consent therefor. Also provides procedures for administering such tests to such persons.

- Requires the State Director of Health to determine and approve methods for chemically analyzing bodily substances, in order to determine blood alcohol content. Also authorizes him to determine necessary qualifications of persons to conduct such analyses. And requires him to issue revokable permits to such persons authorizing them to conduct tests. Limits withdrawals of blood for testing to registered nurses or physicians. Permits breath or urine samples to be taken by other persons.

- Authorizes courts to admit evidence on concentration of alcohol, if taken within two hours of violation.

20909

Provides that a concentration of .15 per cent by weight of alcohol in a person's blood is presumptive evidence of such person's intoxication. Provides that a lesser concentration does not constitute such a presumption, but may be considered along with other evidence in determining the person's guilt or innocence.

- Requires that test results be made immediately available to the person or his attorney, if requested. Permits the person to choose another qualified person to administer tests in addition to those directed by a police officer. And provides that failure to obtain additional tests does not preclude the admission of evidence relating to the police department's test.

- Requires driver's licenses to be suspended for a minimum of 30 days for driving while intoxicated (also for traffic homicide by vehicle, perjury, false affidavits, all felonies relating to or involving motor vehicles, and also willfully fleeing a police officer). Also requires that persons convicted of driving while intoxicated receive the prescribed fine and jail sentence (of present law), in addition to the required driver's license suspension.

Special Note: The term "alcohol" has replaced "intoxicating liquor" in the Ohio Code provisions covering drunken driving (Sec. 4511.19). Also, it is now against the laws of the state for any person to consume any beer or intoxicating liquor in a motor vehicle.

SPECIAL DRIVING PROBLEMS

Night Driving

1. The most important precaution to observe for safe night driving is to drive at a cautious, reasonable speed, so as to be able to stop within the distance illuminated by your headlights, should any unexpected hazard appear out of the darkness.
2. Turn on driving lights immediately at sunset, or earlier if twilight visibility is poor.
3. Dim headlights for every approaching vehicle, and when closely following any vehicle. Use the upper beam only for driving in open country with a clear roadway ahead.
4. Watch for pedestrians who may take chances walking along roads or crossing streets because they do not realize that motorists just can't see them.
5. Keep windows clean. The haze and glare caused by lights shining on dirty glass reduce visibility at night.
6. Do not continue driving when sleepy—pull off the road and rest. Fatigue, which slows down perceptions and reaction time, is a significant factor in nighttime accidents.

Winter Driving

1. The first adjustment a driver must make to winter driving is to reduce speed. No matter what road or weather conditions are encountered, a slower speed is the first consideration for safe handling of any vehicle.
2. Be sure that your car is in excellent operating condition. Lights, brakes, windshield wipers, defroster fan, radiator and other parts should be in perfect order, particularly for winter. Use tire chains for severe snow and ice conditions.
3. Open the ventilator or a window just a little. This helps to keep the windshield clear of a fog and guards against possible carbon monoxide leakage.

20910

4. Remember:
   a. Shaded spots on the highway will retain frost and ice when the other portions of pavement are dry.
   b. Bridges will take on frost and retain ice when the rest of the road may be in a safe condition.
5. To prevent skidding when a sudden stop is necessary, apply the brakes lightly and intermittently. This "pumping of the brakes" will reduce momentum without losing traction and without locking the brakes.
6. To start a car on ice, release the clutch slowly, since the tires will have a better chance to grip if the wheels are turning slowly. Starting in second gear will also help.
7. When driving in a snow storm or fog, use the lower headlight beam. The high beam reflects the snow or fog, while the lower beam reduces the amount of reflection. Fog lights, incidentally, are a good investment.
8. Double the distance at which you normally follow behind another vehicle. This is necessary because of the increased distance needed to stop on slippery pavements.

Left of Center On Roadway With Obstruction

When obstruction exists, making it necessary to drive to left of center of highway, right-of-way shall be yielded to vehicles traveling in proper direction on unobstructed portion.

EXPRESSWAY/FREEWAY DRIVING

A new era of driving lies ahead. Superbly-engineered arteries, arrow-straight, like concrete ribbons, allow the traveler, weary from bucking bumper-to-bumper traffic on congested Main Street, to breeze with amazing time saving across the countryside. Expressway/freeway driving is different from the stop-start routine the motorist finds on the normal humdrum roadway. Expressways force the motorist to adjust to a higher speed of travel. Here are some pointers on expressway driving:

How to Get On An Expressway (See diagram)

(1) Slow down and look before turning into an expressway approach.

(2) If you make a mistake, you must proceed with traffic until you reach the next intersection. Leave the expressway and re-enter by the proper approach.

(3) Wait for a let-up in the traffic stream. Expressway drivers are traveling faster than ordinary city drivers.

(18)

20911

EXPRESSWAY/FREEWAY DRIVING ILLUSTRATED

The Traffic Movement

(1) Pick your lane—and stay with it. Observe and obey signs.

(2) Faster travel means that you'll need more room between you and the car ahead in case of emergency. Follow no closer than one car length for every 10 miles of speed. Pass lawfully and safely.

(3) Stay within the posted speed limit, but be careful that you don't become a traffic hazard by driving too slowly.

(4) Watch for signs noting changes in speed limits. A "slow zone" signals a a danger area.

Fatigue

Be on your guard against highway monotony. Drive with the window open; shift your gaze; play the radio and engage in light conversation to keep alert. Stop periodically to stretch your legs and have a cup of coffee, milk or a cold "soft" drink.

How to Get Off An Expressway

(1) Watch for advance signs for your proper turn-off and move to the correct lane.

(2) Decrease your speed and signal your intention of turning.

(3) Drive slowly, or stop if necessary, before you enter traffic on the cross highway.

Skidding

Precautions taken against skidding are much simpler than steering out of one. However, when a vehicle does go into a skid, take your foot off the accelerator (never apply brakes) and turn the steering wheel in the direction of the skid.

Weaving

Weaving in and out of traffic lanes is a dangerous habit practiced only by the exhibitionist, or the inexperienced or discourteous driver. It actually gains for the driver no more than a few seconds, and causes sudden stops, near sideswipes and irritation among other drivers. Stay in the proper traffic lane and overtake and pass other vehicles only when the roadway ahead is clear.

One-Arm Drivers

Proper control and handling of a vehicle is achieved only when both hands are on the steering wheel. The safety of all occupants of a car, should any road hazard or emergency appear, is very uncertain when the driver is steering with one arm only. It is said rather humorously, but it may well be a fact, that "One-arm drivers are usually headed for the church aisle; some walk down it, others will be carried."

59 20912

What To Do If A Tire Blows Out

A blow-out when traveling at a high rate of speed is dangerous, especially if the driver does not know what to do and becomes frightened. First of all, do not jam on the brakes and do not throw out the clutch. Keep your foot off the accelerator and let the vehicle coast against the engine to stop. When the blow-out is a rear tire, sudden application of the brakes will set up a "tail-sway" difficult to control and the vehicle is likely to turn over. Various types of safety tires may well be considered as important accessories.

When Wheels Run Off Pavement

If a vehicle's wheels run off the pavement onto the berm or soft shoulder, do not try to jerk the wheels immediately back onto the road. Stop accelerating without throwing out the clutch. Allow the engine to slow the vehicle so that it can be pulled safely back onto the pavement.

When Rounding a Curve

Never apply the brakes while you are rounding a curve but apply them before entering it. You may accelerate slightly on the way out of the curve—this extra power will offset the side-thrust of centrifugal force. It is not possible to apply brakes safely while in the process of rounding a curve.

No Coasting

Never coast down a grade in neutral gear. Shift into second gear when going down a steep hill. Coasting not only causes quicker wear-out of the brakes, but increases the possibility of an accident.

Funeral Procession

The following requirements are necessary for vehicles traveling in a funeral procession in order to be recognized and given right of way by other traffic: Each vehicle in a funeral procession must have its headlights lighted and display a purple and white pennant, so as to be visible from any direction.

The Blind Person As A Pedestrian

Watch out for persons carrying white canes or white canes with red tips. The blind are the only pedestrians authorized by law to carry white canes and the law further provides that the blind carrying such canes, as well as those led by guide dogs, are to be given the right-of-way by every driver.

Walking Along Roadway

Persons walking along or upon the highway where sidewalks are not provided must face approaching traffic.

ACCIDENTS

In case of accident on a public road or highway the law requires you as a driver to stop, give your name and address, the name and address of the owner and registration number of the motor vehicle, to the injured person or any person involved in the accident or to a police officer at the scene. You must also display your driver's license or furnish satisfactory proof that you are licensed.

In case of an accident with an unoccupied or unattended motor vehicle you shall securely attach the information required to be given in writing, to a conspicuous place in or on the unoccupied or unattended motor vehicle which was struck.

The operators of all motor vehicles, including non-residents, when they become involved in an accident, resulting in the death or injury to a person or property damage in excess of $100.00, must within 30 days after such accident, file a written

20913

report with the Registrar of Motor Vehicles. Official forms may be obtained from any Government subdivision, Police Department, State Highway Patrol Post, or Deputy Registrar.

FINANCIAL RESPONSIBILITY

Insurance requirements: $12,500 for bodily injury or death of one person in any one accident; $25,000 for bodily injury or death of two or more persons in any one accident; from $7,500 for property damage, and the amount of $30,000 to be deposited with the state treasurer as evidence of financial responsibility.

TRUCK REGULATIONS

The law requires enough space between a truck or a vehicle drawing another vehicle to permit an overtaking vehicle to enter and occupy without danger.

The law requires that operators of motor vehicles carrying passengers for hire, or of any school bus or of any vehicle carrying explosives or inflammable liquids before driving across any railroad grade crossing to:

Stop and listen through an open door or window and look in both directions. He shall cross in such a gear that will not require changing and shall not shift gears while crossing the tracks.

The Director of Highway Safety has the authority to prescribe clearance markers, reflectors and stop lights on buses, trucks, and trailers not operating under the Public Utilities Commission of Ohio.

The law requires a light at night or a flag in the daytime on the load overhang on the rear of a vehicle when the load extends four feet or more beyond the bed of such vehicle.

The following safety equipment shall be carried in all trucks:

1. At least 3 flares, or 3 red reflectors, or 3 red electric lanterns.
2. At least 3 red burning fusees, unless red reflectors or red electric lanterns are carried.
3. At least 2 red cloth flags not less than 12" square with standards to support them.

You, as a truck driver, must take the following steps in case of a breakdown on the highway.

1. Place a lighted fusee or red reflector on the traffic side of the vehicle unless the red electric lanterns are used.
2. Promptly place three lighted flares or red reflectors or three red electric lanterns as follows:
   One at a distance of forty paces to 100 feet to front and one of equal distance to the rear and each in the center of that lane and one on the traffic side of the vehicle. Red Flares shall be used when lights are not required. One shall be placed forty paces or 100 feet to the front and one equal distance to the rear and both in the center of that traffic lane. If disabled, near a curve, crest of a hill or near an obstruction to view, the flags or flares shall be placed to give ample warning, but never less than forty paces or a hundred feet or over one hundred and twenty paces or three hundred feet from the vehicle.

When driving a motor vehicle and hand signals are not visible both to the front and rear, mechanical turn signals must be installed.

Mechanical turn signals must be installed on a vehicle when the distance from the center of the steering post to the left edge of the vehicle exceeds 24 inches and/or when the distance from the center of the steering post to the rear of the vehicle exceeds 14 feet.

20914

No vehicle shall be driven on the highway unless it is so constructed or loaded as to prevent any of its load from dropping, sifting, leaking or otherwise escaping.

Any commercial car, trailer, or semi-trailer, with a gross weight exceeding three tons, including load, must be equipped with suitable metal protectors or substantial flexible flaps on the rearmost wheels to prevent, as far as practicable, the throwing of dirt, water or other materials on the windshield of following vehicles.

The regulations governing towing connections for trailers are: When one vehicle is towing another the drawbar or other connection shall be of sufficient strength to pull all weight towed. In addition to such drawbar or other connections, each trailer or semi-trailer not connected to a commercial tractor by means of a fifth wheel shall be coupled with stay chains or cables to the vehicle drawing it. These chains or cables shall be of sufficient size and strength to prevent parting from the drawing vehicle should the drawbar or other connection break or become disengaged. Every trailer or semi-trailer shall be so coupled that the trailer will follow substantially in the path of the vehicle drawing it without whipping or swerving from side to side. When one vehicle is towing another and the connection consists only of a chain, rope or cable, a white flag or cloth not less than 12 inches square shall be displayed upon such connection.

Any vehicle transporting explosives upon a highway must be marked or placarded on each side and the rear with the word 'explosives' in letters not less than eight inches high, or there must be displayed on the rear of such vehicle, a red flag not less than 24 inches square marked with the word 'danger' in white letters six inches high.

Every such vehicle shall be equipped with not less than two fire extinguishers, filled and ready for immediate use and placed at convenient points on the vehicle.

You must obtain a permit from the Department of Highways if you wish to haul a load on the highway that is larger or heavier than the law allows:

INFORMATION ON LIMITATIONS ON MOTOR VEHICLE DIMENSIONS AND WEIGHTS

Width (except municipal bus or traction engine)	8'0"
Width of municipal bus	8'8"
Width of traction engine	11'0"
Height of all motor vehicles	13'6"
Length of single vehicle (except municipal bus)	40'0"
Length of passenger bus type	40'0"
Length of municipal bus	48'0"
Length of commercial-tractor & semi-trailer	55'0"
Length of any other combination	65'0"

Maximum weight (in pounds)

1. On one axle	19,000
2. Total on two successive axles spaced four feet or less, center to center	24,000
3. Total on two successive axles (tandem) spaced more than four feet apart and less than eight feet, center to center	32,000
4. Total on two successive axles spaced eight feet or more, center to center	38,000
5. Total weight of vehicle and load 38,000 pounds plus an additional 900 pounds for each foot of spacing between the front axle and the rearmost axle of the vehicle.	
6. Three axle group, no more than nine feet	48,000
7. Maximum gross load for any combination of vehicles	78,000
8. Maximum wheel load shall not exceed 650 pounds per inch width of tire.

UNIT IV

SCHOOL BUS ORIENTATION

63 20916

UNIT IV

I. TOPIC

School Bus Orientation

II. ORIENTATION

The school bus driver shall be well acquainted with the bus which he is driving. This includes knowing the characteristics and purposes of the many parts that make up the school bus. Not so important is how the school bus is built, but how well the driver knows the bus and how he can use it properly, safely, and efficiently. This unit will orient the driver to the component parts of the school bus.

III. PRESENTATION

A. The Exterior of the Bus

1. Engine compartment

   a. Fan belt, radiator filler cap, crankcase filler cap, oil measuring stick, distributor, carburetor, generator or alternator, starter, steering gear, and power steering reservoir
   b. Know the location of each item.

2. Wiper blades and arms

   a. Steps and hand hold to reach wipers and windshield
   b. Constantly be aware of the condition of rubber on windshield wipers.
   c. Driver is cautioned not to move electric wiper arms by hand.

3. Warning lights, turn signals, headlights, marker lights, tail lights, and brake lights
4. Front and rear springs and shock absorbers

   a. Shock absorber permits smoother ride with light load.
   b. Condition of springs and shock absorbers should be checked regularly.

5. Transmission, drive line, rear axle, differential, and housing

   a. Each section of drive line is protected by metal guard.
   b. This prevents the drive line from going through the floor or dropping to the ground if broken.

20917

I. Vegetable Cookery

Essential learning (Skill and knowledge)	Scope of instruction (Suggested content)	Information (Technical and related)
How to cook vegetables: The understanding and application of recipes, formulas, and procedures	Preparation: Proper handling and storage of vegetables before cooking	Nutritive value Effect of cooking Preservation of food value, color, flavor, and texture Temporary storage in cold water Equipment and utensils used in cleaning and preparing vegetables
	Procedure for cooking vegetables: Fresh Frozen Dehydrated Canned	Kinds: Leafy Stalk Flower Root Fruit Seed
	Cooking by different methods: Steaming Boiling Pressure cooking Sautéing Braising Frying	Principles involved in: Steaming Boiling Blanching Creaming Sautéing
	Seasoning Temperature Time	Variations
		Sauces used with vegetables
	Proper handling and storage of cooked vegetables	Related science
		Cost factors

Suggested teaching materials: See items 8, 15, 20, 95, 100, 102 in appendix B.

2067

6. Manifold, exhaust pipe, muffler, tail pipe, and hangers
7. Clamps which fasten the body to the chassis frame
8. Tires, rims, lug bolts, and nuts

    a. Recap tires are not permitted on the front wheels of bus.
    b. If used on the rear, it is recommended that a full recap is used.

9. Fuel tank

    a. Minimum capacity 30 gallons
    b. Watch for leaks.

10. Lettering - All black. The right and left side of any vehicle is determined by viewing the vehicle from the rear and the person facing in the same direction that the vehicle is headed.

    a. Name of school district on each side
    b. COUNTY (if local district) on each side
    c. BOARD OWNED - lower right front side
    d. Bus number on each side
    e. Capacity (CAP.) - each side
    f. SCHOOL BUS - 8" letters front and rear
    g. STOP - 10" letters rear
    h. STATE LAW - 5" letters rear
    i. EMERGENCY DOOR - 2" letters - No more than 3" from the top of the door

11. Mirrors - right and left side

    a. Two way adjustable
    b. Cross walk mirrors may be used.

12. Air pressure storage or vacuum storage

    a. Air tank drainage valve
    b. Types

        (1) Hand valve
        (2) Automatic moisture ejector valve

13. Amber and red reflectors

    a. Amber on each side front bottom
    b. Red on each side rear bottom

20918

B. The Interior of the Bus

1. Driver's seat

   a. Adjustment forward and backward
   b. Adjustment upward and downward
   c. Seat Belt

2. Chassis instrument panel

   a. Oil pressure gauge
   b. Ammeter gauge
   c. Speedometer and odometer gauge
   d. Water temperature gauge
   e. Fuel gauge
   f. Illuminated panel, high beam, and turn signal indicator
   g. Air pressure or vacuum gauge with either audible or warning signal

      (1) If warning signal is activated, stop immediately
      (2) Investigate the problem

   h. Light switch, high and low beam foot switch, choke, and throttle control
   i. Ignition switch

3. Body instrument panel

   a. Marker, dome, panel light switches
   b. Warning light master switch

      (1) Manual switch
      (2) Door switch

   c. All heater control switches
   d. Auxiliary fan switches
   e. Wiper motor switches

4. Steering wheel and column

   a. Turn signal switch

      (1) Self cancellation
      (2) Non-cancellation

   b. Horn button

20919

5. Parking brake location and type
6. Gear shift lever and chart of gear locations
7. Clutch, brake, and accelerator
8. Stanchion and grab rails
9. Emergency equipment

    a. Fusees (6 - 30 minute type, encased)
    b. Crowbar or ax
    c. First aid kit
    d. 12" red flags (3)
    e. Dry chemical fire extinguisher (with gauge, 2½ lb. minimum)
    f. 3 red reflectors (encased)

10. Sun visor
11. Interior mirror - adjustable
12. Entrance door and its operation
13. Floor and step well covering
14. Passenger seats

    a. Fiber glass
    b. Upholstered

        (1) Cushion fastening
        (2) Back fastening

15. Emergency door

    a. Operating instruction
    b. Buzzer warning when door is unlatched
    c. Lettering above door 2" high - not more than 3" from the top of the door

IV. SUMMARY

It is necessary for the driver to know the interior and exterior of the bus. He must be familiar with the driver's compartment so that his eyes can focus on the "big picture." Knowing the school bus helps to promote safe and efficient operation. The students deserve the best in transportation; therefore, the driver must be well orientated concerning his vehicle.

UNIT V

DRIVING FUNDAMENTALS

20921

296 OF 327

ED

056 238

MICROCOPY RESOLUTION TEST CHART
NATIONAL BUREAU OF STANDARDS-1963-A

UNIT V

I. TOPIC

Driving Fundamentals

II. ORIENTATION

School bus drivers have entrusted to them the lives and safety of a human cargo that cannot be measured in terms of dollars and cents. The purpose of this unit on Driving Fundamentals is to teach drivers the basic skills necessary for them to operate buses properly in transporting this valuable cargo safely and efficiently.

The individual driver must not only learn these basic driving skills, but the driver must practice each skill correctly in order to become proficient. Through practice, each correct basic procedure will become a habit to the driver and will contribute to the safe operation of the bus. Experienced drivers who have not had the benefit of organized instruction must be made aware of their faults, and each must make a concerted effort to correct any poor driving practices.

In past years, accidents involving Ohio school buses were caused by the school bus driver in over fifty per cent of the cases. This can be traced in large part to driver preoccupation and the absence of organized insturction for the driver.

The instructions which follow have been developed to assist the driver in correctly performing the task of driving a school bus. Each section in this unit is based on sound driving practices and procedures. If properly learned and adhered to, these procedures will result in improving the performance of the bus driver.

III. PRESENTATION

A. **Driver Position** - To be a good bus driver each driver must position himself for comfort, for good vision, and to be within reach of all driver compartment controls.

1. Adjust driver's seat.
2. Adjust seat belt if available.
3. Adjust all mirrors for most advantageous use.

   a. Inside mirror
   b. Outside mirrors should be adjusted so that the driver can see the rear wheel-wells and bumper.

20922

4. The driver should be acquainted with the entire instrument panel and know where each gauge, dial, and switch is located.

B. **Starting the Engine** - The procedure used in starting a bus engine must become a matter of routine. It must incorporate principles of safety and be performed in keeping with good engine preventative maintenance practices.

1. Set parking brake to keep bus from moving.
2. Depress clutch pedal to disengage engine from transmission.
3. Shift gear lever into neutral position to relieve added strain on starter.

   a. Permit additional gears to remain idle.
   b. Check position by moving lever from side to side.

4. Turn on ignition key to complete electric circuits.
5. Engage starter switch.

   a. With clutch depressed and gear in neutral
   b. Use hand choke if necessary and available. Over choking will cause carburetor flooding.
   c. Use foot accelerator sparingly. Pumping will cause carburetor flooding.
   d. Bus engines will vary widely in their carburetor sensitivity; therefore, do not hesitate to ask the supervisor or bus mechanic for special techniques in starting a particular bus.

6. After engine is running

   a. Release clutch pedal slowly without stalling engine.
   b. Allow transmission gears to start rotation.

7. Warm up engine at fast idle.

   a. Do not race the engine.
   b. Much engine wear comes in the first three minutes after starting.

C. **Shifting Gears** - Gear shifting is a phase of bus driving which requires skill and practice. The driver must learn the best range of speed in changing gears upward and downward. Shifting the gears must be accomplished without loss of road vision. Syncro-mesh transmissions have alleviated most of the gear clashing. Generally, buses are equipped with a four or five speed transmission.

1. Know the gear positions.

   a. Check chart on lever knob or on dash.
   b. Ask mechanic.

20923

2. Depress clutch pedal
3. Shift gear lever into starting gear.

   a. For average terrain and load this should be second gear.
   b. Load and/or terrain may dictate the use of first gear.
   c. Never start out in a gear higher than second as this places undue load and wear on the engine and clutch.

4. Depress foot brake.
5. Release parking brake lever. If ratchet type, pull brake lever slightly back to release pressure.
6. Release clutch gradually to friction point and hold. At this point you will have the clutch just at the point of friction and the foot brake on and ready to release.
7. Depress accelerator. Hold point of clutch friction and slightly depress accelerator to increase the power to prevent stalling.

CLUTCH ELEMENTS

Figure 4

20924

8. Release clutch.

   a. Slowly and gradually release the clutch to the remainder of pedal travel and at the same time slowly and gradually increase the acceleration.
   b. Remove foot from clutch pedal completely.
   c. Pick up engine speed before shifting to higher gear.

9. Shift to next higher gear.

   a. Depress clutch pedal and release accelerator.
   b. Shift to next higher gear.
   c. Release clutch smoothly but more quickly than in starting gear and depress accelerator smoothly and quickly.

      (1) To prevent loss of vehicle speed
      (2) Do not race the engine and slip the clutch.

   d. Remove foot from clutch pedal.
   e. Proceed in this gear until proper vehicle speed is reached for shifting to next gear.

10. Repeat #9 procedures until the bus is in cruising gear.
11. Never skip a gear in up or down shifting as this causes undue engine and clutch wear.

Approximate M.P.H. to be reached before upshifting or downshifting. M.P.H. may vary slightly depending on make of engine, transmission, gear ratio, and terrain.

Upshifting		Downshifting	
From 1 to 2 Gear	1 - 5 M.P.H.	From 5 to 4 Gear	30 - 35 M.P.H.
2 to 3 "	5 - 12 "	4 to 3 "	25 - 30 "
3 to 4 "	12 - 20 "	3 to 2 "	5 - 10 "
4 to 5 "	25 - 30 "	2 to 1 "	Stop "

Table 1

20925

12. Shift up or down as may be necessary to prevent engine lugging or excessive engine R.P.M.
13. In going down a hill, shift into the gear that would be used in going up the hill.

D. **Double Clutching** - Syncro-mesh transmissions have almost alleviated the need of double clutching. Shifting the gears on non syncro-mesh transmissions is done faster and smoother by double clutching. This process coordinates the engine speed and transmission speed for non-clashing of gears. Double clutching aligns the gears for easy up and down shifting. The gears should never be forced by improper timing of the shifting process. Reclutching and speeding up the engine will in most cases prevent excessive clashing. The engine should never be allowed to pull heavily going upgrade, on a turn, or on a curve. Neither should it be permitted to over-race downgrade.

1. Double clutching, upshifting

   a. Depress clutch pedal and release accelerator.
   b. Shift gear lever to neutral position.
   c. Release clutch pedal momentarily to engage clutch.
   d. Depress clutch pedal and shift to next higher gear.
   e. Release clutch and accelerate engine at the same time.

2. Double clutching, down shifting (See Table 2)

   a. Depress clutch pedal and release accelerator.
   b. Shift gear lever to neutral position.
   c. Release clutch pedal momentarily to engage clutch and accelerate engine to more than original speed.
   d. Depress clutch and shift to next lower gear.
   e. Release clutch pedal gradually and accelerate engine to match the speed of vehicle.

3. Related items of double clutching

   a. The double clutching procedure may be slow or fast depending upon the type of bus.
   b. Normally down shifting two gears is sufficient.
   c. Double clutching requires continuous practice.
   d. Syncro-mesh transmissions may be double clutched.

E. **Shifting Automatic Transmission** - Some buses are equipped with automatic transmissions and the driver should understand the operation of such transmissions.

J. Salads and Sandwiches

Essential learning (Skill and knowledge)	Scope of instruction (Suggested content)	Information (Technical and related)
How to prepare salads: The understanding and application of recipes, formulas, and procedures	Preparation and procedure: Arrangement Care of salads during preparation Dressings Care of salads after preparation	Nutritive value of salads Types of salads involving use of: Cooked foods Raw foods Gelatin Care in washing and preparing salad greens and vegetables Organization of materials Storage of salad components: Fruits Vegetables Greens Types of dressings Methods of serving Cost factors
How to prepare cold sauces and salad dressings: The understanding and application of recipes, formulas, and procedures	Preparation and procedure: Sauce Seasonings Care during preparation	Variations Equipment Cause of curdling or breaking How to restore curdled mayonnaise
Mayonnaise	Care after preparation	Storage
French dressing	Preparation and procedure: Seasonings Care during preparation Care after preparation	Selection of oils Variety dressings Equipment Storage Cost factors
Cooked salad dressing	Preparation and procedure: Seasonings Care during preparation Care after preparation	Chemical principles involved Shortcomings of cooked dressings Equipment Dressings derived from cooked dressing Storage Cost factors
How to prepare sandwiches and sandwich fillings: The understanding and application of recipes, formulas, and procedures	Preparation of sandwiches: Open face Club Toasted Finger Rolled Hot Grilled Preparation of fillings: Seasoning Care in preparation Arrangement on plate Variety of cuts Care after preparation	Sanitation Handling precautions Variety breads Bread storage Equipment and tools: Type Care Safety precautions Kinds of fillings: Salads Spreads Sliced products Garnishes Storage of sandwiches Storage of sandwich fillings Cost factors

Suggested teaching materials: See items 4, 15, 20, 21, 56, 96, 106, 107 in appendix B.

2068

1. Know the shift positions.
2. Depress foot brake.
3. Move selector lever into forward or drive position.
4. Release parking brake.
5. Release foot brake and depress accelerator.
6. As speed of bus increases, the transmission will automatically shift to the next higher gear until reaching cruising gear.
7. Down shift for additional power.

   a. Depress accelerator to the floor firmly. This will cause transmission to down shift one gear.
   b. Move selector lever to next lower position.

F. **Steering and Turning** - The school bus driver, to be classified as an expert driver, must be able to assume the correct steering position and make all the turning maneuvers correctly and smoothly. He must learn the correct procedures necessary to prepare for the turn, make the turn, and re-enter the traffic pattern. The driver who is confronted with an unusual turn or turn-a-round shall do so with extreme caution. The raising of speed limits and the super highway system in Ohio, upon which the school buses may travel, has forced the driver to use added skills and judgment is making turns properly and safely.

1. Steering positions

   a. Grip the steering wheel with both hands.
   b. Left hand at approximately 10 o'clock position
   c. Right hand at approximately 2 o'clock position

Figure 5

   d. Hands on outside of steering wheel and thembs on top or outside of wheel

2. Focus eyes on road ahead

   a. Eyes should be constantly on the move to obtain the "big picture."
   b. Ahead, left side, right side, rear view mirrors

20927

3. The push-pull steering method is recommended for school bus drivers. One hand pulls and the other hand pushes.
4. Hand over hand method may catch thumb in clothing, safety chain on the wrist watch, bracelets, etc., which are hazards to steering.
5. Preparing for turns

   a. Check traffic to the front and rear of the bus.
   b. Give proper signal to move vehicle into proper lane.

Figure 6

6. Making right turn

   a. Give proper right hand turn signal.
   b. Reduce speed and down shift to proper gear needed to execute turn.
   c. Position bus in right side of the lane.
   d. Check for clear right of way.

      (1) Traffic signals, signs, pedestrians, or vehicles
      (2) Use both outside mirrors.

   e. Execute the turn.

      (1) Make turn smoothly without strain on the engine.
      (2) Never shift gears during a turn.
      (3) Check right mirror while executing turn.
      (4) Enter the right most lane available and check turn signal for cancellation.
      (5) Steer wheels back into position -- do not let steering wheel spin wheels back into position

Figure 7

20928

7. Making left turn

   a. Give proper left hand turn signal.
   b. Reduce speed and down shift gear.
   c. Position bus to the left edge of the lane.
   d. Check for clear right of way.

      (1) Traffic signals, signs, pedestrians, or vehicles
      (2) Use both outside mirrors.
      (3) If necessary to stop, keep front wheels straight and brake pedal depressed.

         (a) Prevent drifting and activate stop lights.
         (b) This will prevent being shoved into line of approaching traffic if struck from the rear.

   e. Execute the turn.

      (1) Drive into the intersection, make turn smoothly, and without strain on the engine.
      (2) Check left mirror while executing turn.
      (3) Never shift gears in a turn.
      (4) Enter the highway in the left most lane available and check turn signal for cancellation.

LEFT TURN
Figure 8

   f. After completing the left turn upon multiple lane highways, pick up speed and move into right hand lane as soon as possible.

8. Making a turn-a-round

   a. Give brake signal well in advance of turn-a-round.
   b. Stop bus in proper position on roadway.

      (1) One bus length ahead of road to be backed into
      (2) Check traffic front and rear.
      (3) Visibility shall be 500 feet in either direction (ORC 4511.37).

20929

(4) Have traffic move around bus if possible.
(5) Back into roadway or driveway using outside mirrors.
(6) Re-enter roadway.

(a) Check traffic.
(b) With caution

TURN AROUND
Figure 9

G. **Stopping and Parking Bus** - Stopping a school bus smoothly and within the limits of safety is another sign of an expert driver. A good driver has his vehicle under control at all times and knows that braking distances increase greatly as the speed and the weight of the vehicle increases. With a reaction time of one second the driver must realize that at 20 m.p.h. the average stopping distance is 59 feet, and at 40 m.p.h. the stopping distance is 179 feet or approximately three times greater. The skillful driver also knows that by using correct stopping procedures the maintenance costs on the braking system will be less.

Table 2

Maximum Safe Stopping Distances for TRUCKS and BUSES In Accordance with ICC Regulations

Speed Miles Per Hour	Feet Per Second	Vehicle Travels (One Second) Reaction Time	Braking Distance	Total Stopping Distance
20	29	29	30	59
30	44	44	67	111
40	59	59	120	179
50	73	73	188	261
60	88	88	270	358
Speed of vehicle.	No. of feet covered per second by vehicle.	Distance traveled in one second before brake can be applied after seeing danger (in feet).	Distance required to stop after brake is applied with good pavement and fair brakes (in feet).	Total feet covered after seeing danger (in feet). Reaction time plus stopping distance.

20930

1. Stopping when is a low gear or 10 m.p.h. and less

   a. Depress clutch pedal and release accelerator.
   b. Apply brakes gradually by increasing pressure.
   c. Reduce brake pressure slightly, but not completely just before coming to a stop to prevent jerking.
   d. Shift gear lever into neutral position.
   e. Release clutch and remove foot from pedal.

2. Stopping when in cruising gear

   a. Release accelerator and depress brake pedal.
   b. When proper m.p.h. is obtained for any gear, down shift to next lower gear. See Table 1.

      (1) Will reduce heat build-up
      (2) Reduce excessive brake wear

   c. Down shifting can be very effective and smooth.

      (1) 3rd gear for 5 speed transmission
      (2) 2nd gear for 4 speed transmission

3. Parking the bus

   a. Shift lever into low gear on level or upgrade.
   b. Shift lever into reverse gear on down grade.
   c. Turn wheels into curb.
   d. Turn off ignition and remove ignition key.
   e. Set parking brake (Parking brake may freeze in wet freezing weather).

H. **Loading and Unloading** - The loading and unloading of pupils presents the driver with additional responsibilities and requires use of good judgment. The driver must learn the proper procedure for controlling traffic, for pupils crossing roadway, for pupils entering the bus, and for pupils seating themselves.

1. Loading

   a. Check traffic - oncoming
   b. Check traffic - behind -- using mirrors.
   c. Activate flasher lights approximately 300 feet before the stop.

      (1) Warn traffic in front and to the rear of the bus in sufficient time.
      (2) This will vary depending upon conditions.

   d. Bring bus to stop using proper procedure (refer to Section G, Number 1 and 2).

20931

e. Do not stop where visibility to front and rear is less than 500 feet.
f. Put gear shift lever into neutral.
g. Re-check traffic to front and rear of the bus and make certain traffic has come to a stop.
h. Open entrance door and signal pupils it is safe to cross in front of the bus.

(1) Pupils should be taught to cross at least 10 feet or 5 paces to the front of the bus.
(2) Instruct child to cross at distance where he can see the driver.
(3) Safety - cross mirrors are helpful.

i. Systematic loading can be very helpful.

(1) Various systems can be used.
(2) Pupil concentration must be considered.
(3) Two pupils per seat starting from rear.
(4) Three pupils per seat starting from rear.
(5) Do not allow students to stand in step well or forward of the driver stantion.

j. Proceed when all students are seated.

(1) Shift into starting gear.
(2) Close the door.
(3) Check to see that all students are seated. Check traffic and move out slowly and smoothly.

2. Unloading

a. Follow the same procedure as outlined in loading under a., b., c., d., e., f., g., h.
b. Proceed when pupils are in complete safety on their residence side of road.

3. Unloading at school building

a. Stop bus using proper procedure.

(1) Place gear shift lever in low gear.
(2) Turn off ignition.
(3) Set parking brake.

b. Do not activate warning flasher lights.

20932

c. Driver stand and face students.

(1) All students remain seated.
(2) Unload front seat entrance side first then front seat driver side. Continue alternating to the rear of the bus.
(3) This unloading procedure promotes safety and efficiency.
(4) Develops good habits in case of emergency evacuation.

If In Full Control, Driver Need Not Deactivate Unit

Figure 10

Shall Deactivate Unit Prior To Turning Sideways

Figure 11

20933

Shall Deactivate Unit Prior To Standing

Figure 12

I. **Railroad Crossing** - Through planned safety procedures for crossing railroad tracks, many accidents could be eliminated. Learn these procedures and practice them until they become automatic actions.

Crossing railroad tracks represents one of the greatest hazards insofar as mass casualities and fatalities are concerned. STOP, LOOK, and LISTEN. All school buses loaded or empty must stop for railroad crossings.

1. Prepare to stop.

   a. Request silence.

      (1) This is a must.
      (2) Turn heaters off if necessary to have more silence.

   b. Get "Big Picture", check traffic control devices.

2. STOP the bus.

   a. Follow stopping procedures.
   b. Stop in a position that gives a clear view of the track in both directions. The front bumper must be clear of the tracks.
   c. Shift into neutral.

3. LOOK and LISTEN.

   a. Open service door and driver's window.
   b. Look and listen through the open window and door.

20934

4. If no indication of approaching train

   a. Shift into starting gear.

      (1) Must be a gear that will take bus across tracks without hesitation.
      (2) Shifting gears on tracks shall not be permitted.

   b. Look and listen a second time, close door, and proceed quickly and smoothly.

5. If there is an approaching train

   a. Hold bus position, may use the parking brake depending on waiting time.
   b. After train passes, follow items under Procedure 4.

6. Multitrack crossings

   a. Make sure no train is approaching on any of the tracks.
   b. After a train passes, wait until other tracks become visible before proceeding. A second train may be approaching from the opposite direction.
   c. Follow items under Procedure 4.

7. Railroad traffic control devices

   a. Flasher lights and bells

      (1) Warning of an approaching train
      (2) If train is stopped or signal is malfunctioning, a vehicle may proceed after driver insures a safe crossing can be made.

   b. Gates

      (1) All traffic must obey these devices.
      (2) Vehicles may proceed around the gates only at the direction of a peace officer or an authorized railroad representative.

   c. Railroad crossing controlled by a flagman

      (1) A school bus must make a safety stop.
      (2) Follow directions of the flagman.

J. **Unusual Weather and Road Conditions** - A good driver will adjust his driving to all kinds of weather and road conditions to stay within the limits of safe driving. Bad weather may excuse a delay, but never an accident.

   1. Conditions causing slippery roads

      a. Rain
      b. Freezing rain
      c. Snow
      d. Wet leaves
      e. Spillage of oil, etc., from trucks
      f. Mud

20935

2. Procedures for safe driving on slippery roads

   a. Slow down.
   b. Use brake fanning action. Sudden braking will cause skidding and loss of steering traction.
   c. Allow more distance for driving action
   d. Allow more distance when signaling.

3. Conditions causing poor visibility

   a. Rain
   b. Snow
   c. Clouds
   d. Fog - Smoke
   e. Inside bus fogging

4. Procedures for safe driving in poor visibility.

   a. Slow down.
   b. Use windshield wipers and defrosters.
   c. Turn on marker lights and head lights.

   NOTE: Driving with lighted parking lights is illegal.

   d. Sound horn at intersections, curves, and other dangerous places.

5. Road conditions caused by freezing, thawing, and rain

   a. Soft and spongy roads
   b. Chuck holes
   c. Broken road sections
   d. Humps

6. Procedures for safe driving on poor road conditions

   a. Slow down.
   b. Be alert for these conditions during the proper seasons.

7. Procedures when driving off roadway onto soft shoulder

   a. Slow down.

      (1) Brake gently.
      (2) Hold steering wheel firmly and steer along berm.

   b. Drive on shoulder.

      (1) Keep bus moving.
      (2) Look for place to pull onto the roadway.
      (3) Check traffic in front and rear.

20936

K. Breads, Pastries, Cakes, and Cookies

Essential learning (Skill and knowledge)	Scope of instruction (Suggested content)	Information (Technical and related)
How to make doughs for bread, rolls, sweet doughs:	General procedure for making various kinds of dough:	Food values of breads
The understanding and application of recipes, formulas, and procedures	Baking powder	Weights and measures
	Yeast	Fermentation
		Yeast
		Care and operation of equipment
How to make bread and rolls	Preparation and procedure:	Types of bread
	Proofing	Types of rolls
	Shaping	Fuels:
	Temperature	Gas
	Time	Electricity
	Care after baking	Composition of flours
		Sanitary factors
		Sugars
		Related chemistry
		Glazes and crust
		Cost factors
How to make baking powder doughs (Quick or hot breads)	Preparation and procedure:	Types of baking powder
	Mixing	Related chemistry
	Handling	Equipment
	Baking temperature	Varieties:
	Baking time	Biscuits
	Care after baking	Muffins
		Corn bread
		Methods of serving
		Regional preferences
		Cost factors
How to prepare basic dessert doughs	Preparation and procedure:	Varieties of cake dough:
	Cakes	Plain
	Cookies	Sponge
	Pastries and tortes	Pound
	Pies	Types of shortening
	Doughnuts	Eggs:
	Cream puffs	Fresh, powdered, frozen
	Eclair shells	Milk:
	Flavorings	Fresh liquid, evaporated, powdered
	Care during preparation	
	Temperature	Equipment and tools
	Time	Storage
	Care after preparation	
	Fillings	Varieties and use
	Frostings	
	Icings	
	Decorations	
		Methods of serving
		Cost factors

Suggested teaching materials: See items 2, 17, 20, 30, 55, 91, 97, 98, 105 in appendix B.

2069

c. Turn onto roadway

(1) Hold steering wheel firmly.
(2) As soon as front of bus is on roadway, return bus to normal position.
(3) Do not allow bus to cross into next lane of the road.

8. Procedures for controlling skid

a. Remain calm.
b. Release accelerator.
c. Do not put on the brakes.
d. Turn front wheel in direction of the skid.

(1) Make smooth turn and not too quickly.
(2) Do not over steer.
(3) This turn will bring front end of bus in line with rear end.

e. Be ready to make the opposite turn as bus begins to re-align with the road.

(1) This turn will need to be made more quickly.
(2) Turn only enough to keep bus in line with the road.

K. **Types of Roads and Speed Limits**

1. Interstate - bus speed limit 55 M.P.H.
2. State Highway and Turnpike - bus speed limit 50 M.P.H.
3. Entering and leaving freeway

a. Use acceleration lane to pick up speed.
b. Yield right of way to roadway traffic - stop only if necessary.
c. Pick an opening in the traffic and move into the flow.
d. To leave the roadway, activate turn signal and move from right lane into deceleration lane.
e. Slow down for exit.
f. Use proper turn signals.

Figure 13 *Diagram from Ontario (Canada) Department of Transport*

4. Multilane and limited access highways - speed limit 50 M.P.H.

   a. These may or may not have short entrance and exit lanes
   b. Entering traffic must yield the right of way.
   c. Exiting traffic must slow down for sharp turn off.

5. Other state roads - bus speed 50 M.P.H.

   a. Seldom have entrance and exit lanes.
   b. Entering traffic must stop.

6. County and township roads - bus speed 50 M.P.H.

   a. The roads will run from good hard surfaced to dirt.
   b. Actual speed will be determined by the conditions of the road.

IV. SUMMARY

Before starting a bus, the driver should have complete vision all around him and be comfortably seated. The driver should be well skilled in the driving fundamentals of the bus before he attempts to drive it. It is his job to transport children and he should do his best to contribute to the safe operation of the bus.

Starting the bus, shifting gears, and double-clutching all require skill and practice. The driver should be able to do this efficiently as he watches the road ahead.

Steering and turning the bus are very important to the driver in his daily routine. He must be able to handle the bus properly whether on a deserted road or a road with heavy traffic. Stopping a bus smoothly and within the limits of safety is another sign of an expert driver. Parking procedures should be known well and practiced.

Loading and unloading presents the driver with additional responsibilities and requires the use of good judgment. He is responsible for the safety of the children on his bus and he must comply to the rules of loading and unloading a bus. He is to get the children <u>to</u> school and <u>from</u> school <u>safely.</u>

Bad weather presents the driver with some additional hazards. However, if the driver realizes the problems involved, he can take the necessary precautions to cope with these hazards.

Procedures before crossing a railroad crossing are extremely important. The driver should watch the railroad signals, open the door, look, and listen carefully up and down the tracks to see if a train is approaching. The parents, supervisors, and children of the community depend on the driver, so he must do his best to operate his bus skillfully and safely to maintain their faith in him.

20938

GLOSSARY

1. Accident - Unplanned occurence that results in property damage or bodily injury.

2. Activate - Start into motion; to make active.

3. Big Picture - The overall view of the traffic situation through the eyes of the driver.

4. Blind Intersection - Intersection of two roadways at which the driver approaching on one roadway cannot see the traffic approaching on the other roadway.

5. Braking Distance - The distance the bus travels from the time braking action is applied until the bus comes to a stop.

6. Center Line - The line down the center of the roadway.

7. City Ordinance - An authorative decree or direction set forth by a municipal government.

8. Cruising Gear - The highest speed gear of any one transmission.

9. Deactivate - To make inactive; to stop.

10. Divided Highway - Multi-lane highway. The lanes that are open for traffic in one direction are separated from the lanes provided for traffic in the opposite direction by a median strip or a physical barrier.

11. Downshift - Shift from a higher gear to a lower gear.

12. Fanning Action - A light pumping action that will not lock the wheels.

13. Freeway - "A divided multi-lane highway for through traffic with all cross roads separated in grade and with full control of access."

14. Highway- "The entire width between the boundary lines of every way open to the use of the public as a thoroughfare for purposes of vehicular travel."

15. Inspection Decal - An emblem issued by the Ohio State Highway Patrol to be displayed on each side of the bus. Issued by patrol after a safety inspection is made of the bus by the patrol and the bus meets the necessary standards.

16. M.P.H. - Miles Per Hour.

20939

17. May - To be able; optional.

18. Motor Vehicle - "Every vehicle propelled or drawn by power other than muscular power or power collected from overhead electric trolley wires, except road rollers, traction engines, power shovels, power cranes, and other equipment used in construction work and not designed for or employed in general highway transportation, hole-digging machinery, farm machinery, threshing machinery, hay-baling machinery, and agricultural tractors and machinery used in the production of horticultural, floricultural, agricultural, and vegetable products."

19. Must - Mandatory; essential; shall.

20. O.R.C. - Ohio Revised Code

21. Preventive Maintenance - Maintenance performed with the intent to reduce breakdowns.

22. Roadway - "That portion of a highway improved, designed, or ordinarily used for vehicular travel, except the berm or shoulder. If a highway includes two or more separate roadways the term "roadway" means any such roadway separately but not all roadways collectively."

23. R.P.M. - Revolution Per Minute of Engine.

24. Shall - Mandatory; must

25. Should - Urgent request

26. State Law - A principle governing action or procedure imposed by the Ohio State General Assembly.

27. State Regulation - A principle governing action or procedure imposed by the State Board of Education.

28. Syncro-mesh Transmission - In a syncro-mesh transmission there is a built-in unit that brings gears into position of alignment for easy shifting as soon as clutch pedal is depressed.

29. Traffic Control Device - "All signs, signals, markings, and devices placed or erected by authority of a public body or official having jurisdiction, for the purpose of regulating, warning, or guiding traffic, including signs denoting names of streets and highways."

30. Vehicle - "Every device in, upon, or by which any person or property may be transported or drawn upon a highway, except devices moved by power collected from overhead electric trolley wires, or used exclusively upon stationary rails or tracks, and except devices other than bicycles moved by human power."

31. Will - A command; an order.

20940

32. Warning Lights (Flasher Lights) - Red lights alternately flashing; used for student pick-up, student discharge, and at railroad crossing.

33. Marker Lights (Clearance Lights) - The amber lights located on upper front corners of bus; red lights on upper rear corners.

34. Four-Way Hazard Flashers - Are activated by hazard switch. Activates all turn signals simultaneously to warn approaching traffic of road hazard.

STRUCTURAL SERIES #1

This course of study was prepared by the Bureau of Industrial Education at the request of the industry, to meet the needs of persons engaged in the supervision and inspection of buildings under construction. Structural Series No. 1 covers one semester's work. This material was developed by the Education Advisory Committee of the California Council of Construction Inspectors Association. This publication is in draft form and will be refined by the Statewide Committee after it has been tested by various instructors.

This material was prepared under the direction of the following committees:

Statewide Educational Advisory Committee

L. K. Berry, Chairman
The Asphalt Institute
Sacramento

Thomas Brassell
Secretary
American Institute of Timber Construction
Palo Alto

Hillis Phillips
Education Chairman
Calif. Council of Construction Inspectors
Stockton

Donald K. Jephcott
Chief Structural Engineer
Calif. State Office of Architecture & Construction
Los Angeles

Gordon Stafford, A.I.A.
Educational Representative
Calif. Council American Institute of Architects
Sacramento

Don Comstock
District Technical Representative
Western Wood Products Assoc.
Baldwin Park

Roderick B. Buchan
District Technical Representative
National Forest Products Assn.
Downey

Donald C. Tillman
Chief Deputy City Engineer
Department of Public Works
Los Angeles

L. Desserts

Essential learning (Skill and knowledge)	Scope of instruction (Suggested content)	Information (Technical and related)
How to make desserts:	Preparation and care of fruits used in desserts	Storage of fruit:
The understanding and application of recipes, formulas, and procedures		Fresh
		Dehydrated
		Frozen
Gelatin desserts	Preparation and procedure:	Equipment, utensils, tools
	Flavoring	Kinds:
	Temperature	Whipped
	Time	Molded
	Care during serving	Fruited
		Methods of serving
	Care after serving period	Storage
Puddings	Preparation and procedure:	Utensils and equipment
	Flavoring	
	Care while cooking	Varieties:
	Temperature	Cream puddings
	Time	Fruit puddings
		Custards
	Care after cooking	Storage:
		Related science
		Bacteriology
		Methods of serving
		Garnishes
Sauces for desserts	Preparation and procedure:	Preparation precautions
	Flavoring	Equipment
	Care in cooking	Cooked sauces:
	Temperature	Varieties
	Timing	Uncooked sauces:
		Varieties
	Testing for doneness	Methods of testing
		Methods of serving
		Storage of hard sauces

Suggested teaching materials: See items 14, 15, 20, 30 49, 55 in appendix B.

M. Appetizers, Canapés, and Hors d'Oeuvres

Essential learning (Skill and knowledge)	Scope of instruction (Suggested content)	Information (Technical and related)
How to prepare cocktails:	Preparation and care of materials	Equipment
The understanding and application of recipes, formulas, and procedures		Storage
		Refrigeration
		Cleaning
Fruit, fruit juice, and vegetable juice cocktails	Mixed fresh fruits	Glassware
	Mixed canned fruits	Silverware
	Fruit supremes	
	Melon supremes	
	Juice cocktails:	Garnishes
	Tomato	Seasoning
	Mixed vegetable juices	Chilling
	Sauerkraut juice	
	Mixed fruit juices	
	Berry juices	Varieties

COURSE OUTLINE
CONSTRUCTION INSPECTION AND SUPERVISION

STRUCTURAL SERIES #1

UNIT I. CONSTRUCTION CONTRACT DOCUMENTS AND PLAN READING (Two three-hour sessions)

A. Objective

1. Objective of this unit is to review for the student the contract documents, their general organization, and to explain the role of the civil and structural plans and specifications as part of these contract documents. The inter-relationship between the architectural drawings and the engineering drawings will be discussed. Considerable emphasis will be placed on the detailed organization of the structural engineering drawings and the proper procedure to follow in getting information from the drawings.

B. Contract Documents

1. Bidding Documents
2. Agreement or Contract
3. Specifications
   a. General Conditions
   b. Special Conditions
   c. Detailed Specifications
4. Plans - Scope of Work Covered
   a. Architectural
   b. Civil
   c. Structural
   d. Mechanical
   e. Electrical
5. Role of Codes and Standards as Part of the Plans

C. General Organization of Trade Technical Specifications

1. Scope of Work
2. General Requirements
3. Materials
4. Workmanship

D. General Organization of Plans

1. Organization of Plans
   a. Order of Presentation
   b. Method of Cross Referencing
   c. Development of Views, Sections, and Details
   d. Use of General Notes, Symbols, and Typical Details
2. Architectural Drawings
   a. Drawing Index
   b. Site Plan
   c. Plans, Elevations, Sections, and Details
   d. Finish Schedules
   e. Door and Window Schedules

20953

3. Civil Engineering Drawings
   a. Topographic and Boundary Survey
   b. Grading Plan
   c. Site Work Plans
   d. Public Works Plans
   e. Coordination with Architectural and Engineering Plans
4. Structural Engineering Drawings
   a. Relationship with Architectural and Engineering Drawings
5. Mechanical Engineering Drawings
   a. Plumbing
   b. Heating and Ventilating
   c. Coordination with Architectural and Engineering Drawings
6. Electrical Engineering Drawings
   a. Line Diagrams
   b. Detailed Drawings
   c. Coordination with Architectural and Engineering Drawings

E. Detailed Organization of Structural Engineering Drawings (Suggested start of second session)

1. Foundation Plans
   a. Spread and Continuous Footings
   b. Pile and Caisson Foundations
2. Framing Plans
   a. Wood
   b. Steel
   c. Concrete
3. Framing Elevations
   a. Wood
   b. Steel
   c. Masonry and Concrete
4. Sections and Details
5. Typical Details and General Notes

F. Supplemental Drawings

1. Structural Shop Drawings
   a. Reinforcing Steel
   b. Structural Steel
   c. Precast Concrete
   d. Others
2. Architectural Shop Drawings
   a. Curtain Walls
   b. Doors and Windows
3. Equipment Drawings
4. As-Builts

INSTRUCTIONAL AIDS

Contract Documents

1. Samples of Standard Forms for General Conditions
2. Contracts, Specifications and Engineering Relations by Mead, Mead, and Ackerman; McGraw Hill Publishers, 1956.

20954

3. For studying plan organization, the preferred procedure will be to have a typical contract set of quarter size drawings for each pair of students.
4. Drawings may be available on 35 mm film for projection on the screen.

20955

UNIT II. SITE LAYOUT (One three-hour session)

A. Objective

1. Objective of this unit is to provide a cursory review of the site layout problem. This instruction shall include a brief description of surveying techniques and principles in preparation of the site and for operations during the construction period. Frequent reference to significant data as found on engineering plans is important to comply with the overall objectives of this unit.

B. Interpretation of Plan Requirements

1. Plot and Site Plans
   a. Property Lines and Dimensions
   b. Contours and Profiles
2. Existing Utilities
   a. To remain in place
   b. To be relocated or remodeled
   c. To be removed
   d. To be abandoned in place
3. Existing Structures and Improvements
   a. Removed
   b. Remodeled
4. Adjacent Structures and Improvements
5. Soil Representations
   a. Soil log and borings
      (1) Water Table
      (2) Stability
      (3) Classification
   b. Excavation and Grading
      (1) Erosion control
      (2) Stability of vertical and slope cut
      (3) Ground water control
6. Sequence of Operations

C. Principles of Surveying

1. Equipment and Tools
   a. Tape
   b. Level
   c. Transit
   d. Rod
   e. Special Equipment
2. General Principles
   a. Measurements
      (1) Linear
      (2) Angular
      (3) Leveling

20956

M. Appetizers, Canapès, and Hors d'Oeuvres—Continued

Essential learning (Skill and knowledge)	Scope of instruction (Suggested content)	Information (Technical and related)
How to prepare cocktails—Continued		
Fish and seafood cocktails	Preparation and care of fish and seafood products used in cocktails	Storage Temperature
	Shrimp cocktail: Island shrimp Jumbo shrimp	Cooking Peeling Cooling Holding time Cost factors
		Preparation precautions Equipment Glass and silverware
Sauces for shrimp cocktails	Preparation and seasoning	
	Types of sauces: Hot (horseradish, pepper) Bland (mayonnaise base) Preparation process	Precautions in preparation Storage after preparation Ingredients
	Crab meat cocktails	Preparation precautions Equipment Glass and silverware
How to make canapés: The understanding and application of recipes, formulas, and procedures	Method of preparation: Treatment of toast or bread Other ingredients: Fish Caviar Seafood Shrimp Gooseliver Cheeses Meats	Precautions: Freshness Temperature Kinds of breads Toasting Use of aspic Method of service Garnishes Arrangement Utensils
How to make hors d'oeuvres: The understanding and application of recipes, formulas, and procedures	Kinds or varieties: Hot: Bacon-wrapped: Pre-cooking Final preparation Bouchees: Puff paste patties Fillings Others: Pastes Stuffed or filled	Varieties: Fish, meat, vegetable, seafood, chicken livers Baking Precautions in filling patties Method of preparing Holding after preparation Serving techniques

Suggested teaching materials: See items 20, 21, 34 in appendix B.

b. Control Points
   (1) Monuments
   (2) Stakes and Ties
   (3) Bench marks
   (4) Lot lines
c. Line and Grade
   (1) Stakes and Markers
   (2) Stationing
   (3) Center line
d. Field Notes
e. Grade Sheets

D. Site Conditions

1. Access to Site
2. Topography
3. Drainage Patterns
4. Temporary Construction Facilities
   a. Utilities
   b. Work Space
   c. Storage and Stockpiling
5. Public Convenience and Safety
   a. Detours
   b. Protective Works
      (1) Utilities
      (2) Adjacent structures and improvements
      (3) Fences

UNIT III. BASIC PRINCIPLES OF STRUCTURAL ENGINEERING AND MECHANICS OF MATERIALS

A. OBJECTIVE

In the coming meetings of this course, the basic requirements for good construction of foundations, concrete work, wood framing, steel framing and masonry work will be covered. These discussions will generally follow a basic pattern. The first item to consider will be the materials that go into each type of construction. They all have specified standards which they must meet. The second step will be to outline acceptable construction procedures for putting these materials together so that they can produce the quality of construction desired.

Now it is important that you understand why these material standards must be met and why the specified quality of construction must be achieved. For example, the specifications may call for all concrete in floor beams to have a twenty-eight day compressive strength of 4000 pounds per square inch and the drawings may show a particular beam to be such and such a size and to be reinforced with two number 8 steel bars conforming to ASTM Specification A432 in such and such location. If you have some understanding of how the designer intended this material to act in supporting its intended loading, it will emphasize the importance of getting the grades of material specified and of controlling the placing of this material so that the beam will have the load carrying capacity the design engineer intended.

In addition, all construction people are called on to do some of their own engineering in the course of putting a building together. When erecting the simplest shoring, temporary bracing or providing rigging for lifting, an understanding of how structural elements (beams, columns, tension ties, etc.) support loads will aid in making a safer and more economical construction system.

It is with this in mind that we present here some of the basic principles of structural engineering. It is not intended that the man doing the inspection will be called on to provide an engineering analysis of the structures he is watching go together. An understanding, however, of the engineering principles used to arrive at the details shown on the plans and to set forth the requirements in the specifications will be useful in interpreting these requirements and in following them out.

This discussion will cover the loads and forces which act on structures and how they are distributed to the various parts of the building such as beams, columns, and bracing elements.

B. LOADS ON STRUCTURES

In the planning of any new structure, be it a building, a bridge, or a dam, one of the primary objectives is that it remain standing during its expected service life.

Most building codes present this as a preamble. Section 102 of Title 21, the "Building Code" for public school buildings, requires that "Every building and all structural parts thereof shall be of sufficient strength to support the estimated or actual imposed loads, including lateral forces, without exceeding the allowable working unit stresses specified in these rules and regulations for the material, -----, or permissible combinations of materials of which said building and structural parts thereof are constructed;". Section 2302 of the Uniform Building Code states a similar requirement.

20958

The first consideration, then, for the structural analysis of a building is to determine what loads will act on it and secondly how these loads will be distributed to its various parts.

One job the structure must do is to support its own weight and the weight of all permanent stationary construction becoming part of the building. This type of loading is defined as "dead" load. Probably this term "dead" was felt to apply because these loads would remain more or less permanently in place on the structure as opposed to other types of forces on the structure which might not act continuously or which might vary in amount and direction.

The service loads, caused by various occupancies, are termed "live" loads and are intended to represent the weight of equipment and occupants on floors and possible snow or water on roofs.

Another very important class of loading is the "lateral" loading which includes earth pressure, wind and earthquake forces.

C. FORCES AND EQUILIBRIUM

Force is that which produces, or tends to produce motion. In buildings and other structures we are interested only in forces at rest or in equilibrium. Equilibrium is that condition in which forces acting upon a body balance one another.

The force by which all bodies are attracted to the center of the earth is the force of gravity. The magnitude of the force of gravity is the weight of the body.

Fig. (1) The weight of the 1000# block is a force downward, and requires a 1000# upward force at the hook to be in equilibrium.

Fig. (2) The beam supporting the 1000# load is held in equilibrium by upward forces at the supports, called reactions. The sum of the two reactions upward must equal the downward force, namely 1000#.

D. STRESSES AND STRAINS

These two terms are often used erroneously and should be clarified. When a force acts on a body, resisting forces are set up in the fibers of the body. These resisting forces are called stresses, a stress being an internal resistance in a body to an external force.

20959

Total Stress on a section through a body is the total internal force on the section measured in pounds, tons, etc.

Unit Stress is the stress per unit area of the section, and is measured in pounds, per square inch (psi), tons per square foot, etc. Unit stress is usually the value referred to in engineering. Building Codes set up allowable unit stresses for all building materials, wood, steel, concrete, masonry, and foundation soils. The engineer must stay within these allowable stresses in designing members.

When a body is subjected to a force, there is a change in the size or shape of the body. These changes in dimensions are called deformation, or strain. They may be very small, but are always present, no matter how small the force.

Strain or Deformation

Fig. (3) When a block is compressed under a force P, it shortens. The decrease in length is the strain, or deformation.

Strain

Fig. (4) When a rod is stretched, it lengthens. The increase in length is the strain.

Total Strain is the total elongation, or shortening, measured in inches, etc.

Unit Strain is the total strain divided by the original length, measured in inches per foot, centimeters.

Type of Stresses

There are three types of simple stresses, known as tension, compression and shear.

Fig. (5) Tension, or tensile stress is caused by a force tending to stretch and lengthen the member.

20960

Fig. (6) Compression, or compressive stress is caused by a force which tends to shorten or push a piece together. A post carrying an axial load is in compression.

Fig. (7) Shear or shearing stress is caused by equal and opposite forces which tend to cause a sliding action of one part of the material past another.

The rivet is said to be in shear.

E. BENDING AND COMBINED STRESSES

So far we have talked about "direct" stresses, resulting from a pull or push along the axis of a member, or shearing stresses from a force at right angles to the axis. Many structural members have several types of stresses working at the same time.

A beam is a member that resists loads by bending. The stresses produced by the bending are called bending stresses or flexural stresses, but are actually partly compressive stress and partly tensile stress.

A simple beam with a load W is shown in Fig. (8). Before the load is applied the beam is straight, but deforms to the dotted position after loading. It can easily be seen that the bottom flange must stretch, and the top must compress. Evidently there is a point where the stress changes from compression to tension, and must therefore equal zero. This is called the neutral axis.

20961

Fig. (9) The bending stress diagram shown in Fig. (9-a) indicates how the maximum stresses occur at the top and the bottom, and change gradually to zero at the neutral axis.

These maximum conditions are called extreme fiber stresses, and are the ones that are designed for by the engineer.

The deformation of a beam under a traverse force is called deflection.

Fig. (9-b) shows a condition of "positive" bending (tension on the bottom fibers, compression at the top). "Negative" bending occurs when the fibers above the neutral axis are in tension, and those below are in compression. (See "cantilever Beams" under BEAM TYPES, next section)

Fig. (10) In addition to bending stresses, the beam has shear stresses.

Vertical shear forces are the force W downward and the reactions upward. The tendency of the longitudinal fibers to slip past each other is called horizontal shear.

The chords of a bruss act similarly to the extreme fibers of a beam.

Fig. (11) As the truss deflects under load W, the top chord goes into compression, and the bottom into tension. This is true of all trusses, except those that are continuous over more than two supports.

20962

F. BEAM TYPES (Classified by kind of support)

1. Simple beam

2. Cantilever

3. Beam overhanging on support

4. Continuous beam

Beams do not have to be horizontal. A vertical window mullion acts as a beam to resist wind load. If the mullion helps support the roof, it also has compression. See Fig. (12).

20963

Fig. (13) shows some obvious examples of different types of stress in a building.

G. BENDING MOMENT

In the same way as we speak of the direct load in pounds or the unit stress in pounds per square inch, so we have the term bending moment to designate the measure of bending action. A moment is the tendency of a force to cause rotation about a given point or axis.

Fig. (14) represents a diving board 8' long, and a 200# man about to dive. As he walks out on the board we can see that the board is "bending", and that the bending increases to a maximum when he reaches the outer end. The weight of the man multiplied by the distance from the support is the bending moment. 200# (lb.) x 8 (ft.) = 1600 ft.-lb. bending moment.

Bending moments may be calculated in a similar manner for other types of beams (simple, continuous, etc.)

The bending moment is used to calculate the bending stresses in beams.

20964

H. MOMENT OF INERTIA AND SECTION MODULUS

These properties of a beam, along with the bending moment, are required before bending stresses can be obtained. The term "moment" in moment of inertia should not be confused with bending moment. The moment of inertia of a beam is complicated in its derivation, but depends only on the physical dimensions of the cross section of the beam. The larger and deeper the beam, the greater the moment of inertia, and the greater the resistance to bending moment. Section Modulus is the Moment of Inertia divided by the distance from the axis to the extreme fiber.

Fig. (15) The moment of inertia of any rectangular cross section is $\frac{bh^3}{12}$.

For this beam, moment of inertia $(I) = \frac{3x(4)^3}{12} = 16$ in.

Distance (c) from neutral axis to extreme fiber = 2 inches.

Therefore, Section Modulus (S.M.) $(S.M.) = \frac{16}{2} = 8$ in.

Beam bending stresses may be calculated by means of a formula involving bending moment and Moment of Inertia or Section Modulus.

$$\text{Bending stress} = \frac{\text{(Bending Moment)}}{\text{Moment of Inertia}} \times \text{extreme fiber distance c)} = \frac{Mc}{I}$$

$$\text{or Bending Stress} = \frac{\text{Bending Moment}}{\text{Section Modulus}} = \frac{M}{S.M.}$$

It can easily be seen that the larger the moment of inertia or section modulus, the smaller the bending stress. Deflection of a beam is likewise cut down as the moment of inertia increases.

I. BEARING AND COLUMN ACTION

Fig. (16a) The column shown in Fig. (16a) is in compression, and exerts a a bearing force on the floor, which the floor in turn exerts upward on the end of the column. Allowable bearing stresses are given in Building Codes, and

20965

vary with different materials as do the other stresses. An excessive bearing stress tends to crush the fibers of the material in the immediate vicinity of the application of load. (Fig. 16b)

Fig. (17) However, as a column gets longer and longer, it tends to buckle sidewards. Then the failure of the column will result from a buckling rather than a crushing of fibers at the top and bottom. Therefore, a short fat column must be checked for bearing, and a long slender one must be checked for buckling. (Fig. 17)

J. YIELD POINT, ULTIMATE STRENGTH, SAFETY FACTOR

When a force is applied to a member it deforms, and when the force is removed, the member springs back to its original dimension, the same as a rubber band. The stresses are said to be within the elastic limit. If forces are increased until the member no longer springs back to its original dimensions, but stays permanently deformed, the stresses are said to have passed the yield point. If still further force is applied until the member is completely broken or collapsed, the ultimate strength has been exceeded.

Neither of these latter two conditions can be tolerated in structures, so all stresses must be in the elastic range. The Safety Factor of a member is the numerical ratio between the ultimate strength (or sometimes yield point) and the actual stress in the member. If a concrete member has an ultimate strength of 300 psi and is stressed to 1000 psi, the ultimate strength safety factor is $\frac{3000}{1000} = 3$.

If the yield point of a steel member is 33,000 psi, and the member is stressed to 20,000 psi, the yield point factor is $\frac{33,000}{20,000} = 1.65$. Thus Safety Factors may be referenced to either ultimate strength or to yield point.

20966

Area II

SCIENCE RELATED TO FOOD PREPARATION

Area II outlines the essential scientific knowledge applicable to food preparation. The student must have an understanding of the relationship between cooking as an art and the several sciences.

Food production people need a working knowledge of the chemical and physical changes that take place in the preparation and service of food. Hygiene and sanitation play an important role in the storage of food, the prevention of food poisoning, and the control of rodents and insect infestations. The instructor should teach students to realize that high standards of personal hygiene are essential in food service. The relationship between good personal health habits and food sanitation should be emphasized.

Area II contains three subdivisions:

A. Nutrition.

B. Food Chemistry.

C. Hygiene and Sanitation.

Related information important to an understanding of sound cooking procedures is presented for each subdivision.

A. Nutrition

Essential learning (Skill and knowledge)	Scope of instruction (Suggested content)	Information (Technical and related)
To know the basic principles of nutrition	Nutrition as a science	Soil conditions, climatic conditions, and preparation methods which influence food values
	Nutrition as related to food preparation and service	
	Function of food	Metabolism
	Importance of food and diet to health	
To know the value of nutrients	Carbohydrates:	
	Composition and sources	
	Classification	
	Effect of deficiency or excess	
	Effect of cooking	
	Digestibility	
	Fats:	
	Nature and composition	
	Sources	
	Digestibility	
	Effect of cooking	
	Proteins:	Quality proteins
	Composition	
	Sources	
	Function	
	Effects of deficiency	
	Effect of cooking on digestibility	
	Acceptability	
	Minerals:	
	Sources	
	Functions	
	Dietary requirements	
	Effect of shortage	
	Water:	
	A nutrient agent	
	Food sources	
	Body functions	

2072

SESSION 2

K. DEAD LOAD

The determination of dead loading for a member in a structure is relatively simple. It consists basically of finding the volume of material for each element of the structure and then multiplying this volume by the unit weight of the material. Take an isolated concrete beam for example. (Fig. 18)

18

This beam is seen to be 2.0 feet wide by 5.0 feet deep by 100 feet long. First we compute its volume per foot of length using cubic feet as a convenient unit of measurement.

Volume = 2.0 ft. x 5.0 ft. x 1.0 ft. = 10 cu. ft./$_{ft.}$

Next we determine the unit weight of material. We can find in various handbooks that heavy rock concrete weighs approximately 150 pounds per cubic foot of volume.

The dead load per linear foot of beam is then:

W = 150 lbs. / cu. ft. x 10 cu. ft./$_{ft.}$ = 1500 lbs./$_{ft.}$

L. LIVE LOAD

The live load or service load for floors and roofs would normally be taken from a building code which has compiled weights of probable concentrations of people and/or equipment per square foot of area for various uses and occupancies. The amount of this loading depends on the loaded area tributary to the member being analyzed. Some representative values taken from Title 21 are listed below:

Type of Loading	Pounds per square foot
Roof Loads	Snow load but not less than min. of 12-20
Classrooms	50

20967

Type of Loading (Contd.)	Pounds per square foot
Assembly Halls (level floor) . .	100
Storage Area	Actual loading but not less than 100

An example of storage area loads can be realized by checking the weight of stacked books. A six-foot high stack of solidly packed books weighs:

65 lbs./cu. ft. x 6 ft. = 390 lbs./sq. ft.

A mezzine, then, to be used for storing books should be designed for, say, 300 lbs. per sq. ft. which allows for aisle space.

M. LATERAL LOADS

The general statement we just mentioned from Section 102 emphasizes the inclusion of lateral forces in designing our structures. The reason for this emphasis is that the effects of these lateral forces have all too often been forgotten in the past.

It seems that people in the construction field, be they designers, contractors, or inspectors, have a pretty good understanding of the effect of gravity or "vertical force" loading. After years of experience they develop a "feel" for its action on structures and usually have a basic understanding of how a building should be put together to resist the action of these vertical forces.

Through all recorded history, however, we find that builders have had trouble with the action of lateral forces such as wind, earthquakes and water. Possibly this is because these particular forces of nature in their more violent forms occur infrequently and for short periods of time. As a result, it was difficult to study the ways in which the high winds, the hurricanes and our earthquakes acted to destroy buildings.

Today we can describe these forces in terms of "idealized" loadings and show how our buildings can be put together to resist them.

N. EARTHQUAKE LOADINGS

The action of earthquakes or oscillating ground motions on buildings can best be demonstrated by "idealizing" our typical building into a simple frame as shown in Fig. (19).

20968

By "idealizing" the action of the earthquake into a simple horizontal motion of the ground surface, its effect on our "building" can be studied. Consider first what happens when the ground moves slowly back and forth under the building. The mass supported on the columns moves with the ground. There is relatively little deflection or bending of these columns. The deflection that does occur can be shown as being equivalent to that of a small horizontal force applied to the mass (Fig. (20a). Now if the ground is moved rapidly, the mass lags behind and the deflection or bending of the columns is large. This action can be represented then by a larger force which, as shown in Fig. 20b, will be proportional to the deflection.

20 A

20 B

Thus by using the proper magnitude of horizontal force and applying it on our structures at points which will give equivalent deformations, we can represent our earthquakes by a system of static forces. A similar example of the type of forces involved is one we feel every day when we bring our car to a stop, especially if we are wearing a safety belt and stop suddenly.

21

07203 20969

FIG. 23B - ROOF ACTION AS HORIZONTAL BEAM

FIG. 23A WALL ACTING AS VERTICAL BEAM

FIG. 23C - END WALL ACTING AS VERTICAL BRACE

SOA-181-
20970

The force or load placed on the safety belt depends on two things, the rate at which the car was slowed down and the weight of the person held by the belt.

In designing buildings the size of horizontal force or load used is a function of the stiffness of the bracing system and weight of the supported structure. The method of arriving at these exact values are not necessary to understanding the underlying principles of "quake-resistant" construction although it is necessary, of course, for the designing engineer to determine their values within reasonable limits.

We can carry our study one step further by considering our idealized building in its three dimensions. While there are any number of framing systems with a wide variety of bracing methods to choose from, this analysis will be limited to the simple "box" type which is a very common type of building consisting of bearing walls and a flat roof.

22

The earthquake motion will be studied perpendicular to the side walls.

To start our analysis we apply a horizontal force to the side walls. This size of this force is determined by assuming the wall has "horizontal weight" and the amount of force generated by this horizontal weight is a fraction of the walls vertical weight. As shown in Fig.(23a), this equivalent horizontal force must be resisted by a reaction at the foundation and a reaction at the roof. If the wall is not held at the top by a roof or the connection to the foundation is not adequate, the wall may topple over.

Now we turn our attention to the roof framing. The reaction from the wall is equivalent to a horizontal force applied to the edges of the roof. In addition, the motion caused by the earthquake generates "horizontal weight" in the roof construction which we show as equivalent horizontal force. Two conditions must be satisfied if the building is to remain standing under the action of these forces. First, the roof construction must be capable of acting as a horizontal beam. This can be done by providing diagonal members to make a horizontal truss or by connecting together the sheathing material to make it work as a shear carrying diaphragm. Secondly support must be provided which can restrain the horizontal reactions. In the simple building example, this is done at the end walls. (Fig. 23c) These end walls must be designed to work as a vertical bracing system which cantilevers

up from its foundations. This bracing system may be in the form of diagonal braces or a shear carrying diaphragm commonly called a "shear wall."

The effectiveness of this system of framing depends on two items. One, the strength of the structural elements making up the bracing systems and, two, the strength of the connections between the various components. If either one of these two items is not properly taken care of in the building, there is the possibility of failure when an earthquake comes along. The old adage that "a chain is no stronger than its weakest link" certainly applies to this situation.

O. WIND LOADING

The effect of moving air or wind on a structure is actually a complex problem in aero-dynamics and a host of investigators have wrestled with the subject. Without going into the background of its development we can say that for most structures the reaction between wind and an object in its path can be simulated by an air pressure loading on the exposed surfaces.

Visualize a wall surface forming one end of a square tank. If we pressurize this tank up to 15 pounds per square foot the loading on the wall will be equivalent to the velocity pressure of a 75 mile per hour wind and is the minimum required loading for buildings (not more than 60 feet above ground) by Title 21.

On exposed framing and isolated structures such as towers, signs and floodlight poles the wind exerts a drag or friction force in addition to the velocity pressure force. This has been simulated for design purposes in Title 21 by increasing the pressure loading to 25 pounds per square foot on the gross area of the projected surface of the structure.

The development of framing systems in buildings to resist this wind pressure loading is similar to that discussed for earthquakes. Usually one or the other of the two types of lateral loadings will control and one design will be adequate for both sets of forces.

P. LOADS ON BUILDINGS

Live Load (Temporary loads, such as rain, snow, piles of building materials, etc.)

Dead Load (Actual weight of building materials)

20972

Vertical Loads

Vertical loads consist of Dead Loads and Live Loads, and are applied downward vertically. In the sketch, the rafters support the sheathing, roofing, insulation, ceiling, etc. Rafters rest on a longitudinal beam and outside bearing walls. The beam load is carried by columns which rest on pier footings, and the bearing wall rests on a continuous spread footing.

Wind Loads

Wind is applied horizontally against the vertical projection of the building. The wall is held against wind at the bottom by its fastening to the sill plate, and at the top by its fastening to the roof.

Fig. (25) The roof must carry the horizontal reaction due to 1/2A and the wind load B on the roof itself

20973

Fig. (26) This load must be carried through the roof by a diaphragm or horizontal bracing system to the end walls, or other shear walls.

The end shear walls react against the roof horizontal load, and carry this horizontal force to the foundation by plywood or diagonal sheathing on the wall, or a bracing system in the wall. Thus the horizontal force is carried to the ground, where <u>all</u> types of forces on a building must eventually go.

20974

TERMS AND DEFINITIONS

Force: Force is that power which changes or tends to change the state of rest or motion of a body or causes a body to change its shape if held in place by other forces.

Work: Work is the product of force and distance or force acting through distance.

Stress: Stress is a distributed force. It is a measure of force per unit of area.

Fiber Stress: Fiber stress is the distributed force tending to compress, elongate or change the relative poisition of fibers.

Tension Stress: Tension stress is an internal stress induced by forces which tend to elongate the affected member.

Compression Stress: Compression stress is an internal stress induced by forces which tend to crush or shorten affected members.

Shear Stress: Shear stress is an internal stress induced when opposing forces tend to cause adjoining planes or surfaces of a member to slide, one on the other.

Allowable Unit Stress: Allowable unit stress, varicusly called safe working stress, working stress and allowable stress, represents the maximum stress which may be safely induced in a material.

Strength: In a broad sense the term "strength" embraces those properties of a material which enable it to resist imposed forces or loads.

Bending Strength: Bending strength is a measure of the load carrying capacity of a beam.

Bending Stress: Bending stress is a compound stress induced by loads which tend to cause the member to deflect, as a beam.

Stiffness: Stiffness is the property which enables a member acted upon by external forces to resist deformation.

Flexibility: Flexibility is the quality which renders a material capable of being appreciably bent without breaking.

Elasticity: Elasticity is the property which permits changing form with the application of force and immediate recovery upon release.

Plasticity: Plasticity is that property of material which permits it to develop a permanent set or change in dimensions whn an external force causing a change in length, shape, or volume is removed. Plasticity is the opposite of elasticity. Lead is a material having this property.

20975

Vector: Vector is an arrow used to indicate the amount and the direction of a force.

Equilibrium: Equilibrium is the state of balance of forces acting on or in a body resulting in a state of rest, the resultant force being equal, mathematically.

1000 lbs. + 1000 lbs. = 0

Strain: Strain is sometimes called "deformation". It is the change in the length of a body caused by internal stress induced by an external load.

Total Strain: Total strain is the sum of all the resulting strains in the body under strain.

Unit Strain: Unit strain is the intensity of the strain per unit of length of the piece.

Kip: Kip is a unit of force equal to 1000 lbs.

Bending Moment: Bending moment is the tendency of a force to cause rotation about a given point or axis (Force x Length = ft. lb.) bending moment.

Yield Point: Yield point is that point when a member subjected to forces no longer springs back to its original dimensions.

Ultimate Strength: Ultimate strength is the moment when further force is applied the member collapses. Failure by breaking indicates that the "ultimate strength" has been exceeded.

Live Load: Live loads are those loads imposed on a structure by rain, snow, workers, material, etc.

Dead Load: Dean load is the actual weight of the materials permanently attached to the building.

20976

A. Nutrition—Continued

Essential learning (Skill and knowledge)	Scope of instruction (Suggested content)	Information (Technical and related)
To know the value of nutrients—Con.	Vitamins: Composition Functions Food sources Effect of deficiency Effect of cooking Effect of freezing Loss of vitamins in cooking and preparation Prevention of loss	Enriched flours Enriched margarine Revitalized food Irradiated milk Demineralized foods Devitalized foods Vitamin fortifications
To understand the role of calories in the diet	Energy requirements of individuals: Physical activity Age Sex Body structure Weight and size	Formula for calculating caloric requirements Effect of: Cooking Storage Exposure
To know dietary balance and analysis	Importance of well-balanced food combinations Necessary nutrients Caloric content of foods Percentage retention after cooking	A daily food plan or foundation diet How dietary balance is accomplished Method of calculating required amount How to calculate Food habits Fads and fallacies
To understand digestion of food	Digestive system: Digestive juices Enzymes in digestive juices: Types and functions Absorption Digestion and health habits Proper eliminations	

Suggested teaching materials: See items 7, 11, 22, 24, 25, 33, 35, 47, 74, 79, 87, 101, 111, 113 in appendix B.

UNIT IV - SOIL FUNDAMENTALS

Teaching Outline	Techniques, Aids Devices & References
A. Introduction to Principles & Terminology	
1. History of Soil Mechanics	See Appendix I - Soils
2. Definition of Soil by Engineers	MS-10, p.5
	PCA Soils Primer, p. 9
a. Any earthen material excluding solid rock	
b. It is composed of loosely bound mineral grains of various sizes and shapes, organic material, water and gases.	
3. Composition	
a. Solids, Water and Air	Diagram, p. 9 - Soils Manual - MS-10
b. Solids	
(1) Weight of the oven dried portion at 230°F.	
(2) Dry to constant weight	
(3) Temperature critical - do not break down water of crystallization	
c. Water	
(1) Internal in grains	
(2) Films around surface of grains	
(3) Voids between grains	
(4) Saturation	
(a) Displaces all air, leaving water and solids	
(b) Show by diagram	

20977

d. Air

(1) All soils contain some air

4. Size

a. Varies from boulders (12" dia +) to colloidal clays (1 micron or less)

b. Smallest particle size visible 0.074mm or 200 mesh

c. Divided in coarse grained soils (200 mesh +) and fine grained soils (200 mesh -)

5. Shape

BuRecl Earth Manual, p.4

a. Bulky grains (coarse grained)

(1) Rounded and subrounded; angular and subangular

b. Flaky grains (fine grained)

c. Elongated grains and fibers (fine grained and organic)

6. Source of Soils

a. Formed by decomposition of rock due to weathering into residual soils

b. Residual soils are transported by wind (aeolian), water (alluvial, marine, lacustrine) and ice (glacial till).

c. Sometimes reformed to sedimentary rocks by overburden pressures

7. Identification and Classification

a. Purpose

(1) Group soils with similar performance characteristics

20978

(2) Provides a reference standard (measuring tool) common denominator

b. Systems

(1) Five basic systems — PCA Soil Primer, p. 10

(2) We will study unified because most used by soils engineers — See Table VI-1, MS-10, and Chapter VI, MS-10

(a) Will be discussed later in more detail

c. Terms — For expansion see Glossaries in references

(1) Coarse grained soils

(a) Boulders (12" +)

(b) Cobbles (12" x 3")

(c) Gravel or crushed rock (3"x#4) (#4 is about 3/16")

(2) Sand

(a) Coarse #4 to #10, Concrete

(b) Median, #10 to #40, Plaster

(c) Fine, #40 to #200 Table salt and sugar

(3) Fines (Silts, Clays and Colloids, passing 200 mesh) like flour for baking

8. Properties

a. Internal Friction - is the resisting force in a soil mass due to particle roughness. In shear testing it is a constant quantity for a given normal force and the strength is usually expressed as the tangent of the angle of internal friction or the friction — Hough, p. 147; MS-10, p. 12

20979

angle. The friction angle remains essentially constant.

b. Cohesion - is the part of shear strength that is not due to friction. It is a variable quantity being 0 in clean sands and gravels (no fines) and increasing as silt and clay contents increase. For any given soil the cohesive force will vary with moisture content, rate and time of loading, confining pressures and other factors. The mutual attraction of the particles of a soil to each other in the presence of moisture.

Coulomb's Law

$s = c + p \tan \emptyset$

Hough p. 162

MS-10 p. 12

Use Fig. 6-17 Hough p. 163 to illustrate

c. Capillarity - is usually referred to as the rise in moisture in a fine grain soil above the level of free moisture or the water table. Inasmuch as capillaries (tubes) are small, capillary rise occurs in fine grain soils.

d. Elasticity, Plasticity, Compressability & Compaction -

(1) Elasticity is the ability of a soil to return to its original shape after being deformed by a load for a short period of time.

MS-10, p. 10

(2) Compressability in soils, refers to that part of volume change resulting from the expulsion of pore water. Consolidation is also used to describe this volume change. (Takes time to consolidate).

MS-10, p. 13

20980

(3) Compaction in soils, refers to that part of volume change resulting from the expulsion of air. (Can generally be accomplished in a short time period). — MS-10, p. 13

(4) Plasticity is the ability of a soil to be deformed rapidly without cracking or crumbling and maintain the deformed shape after the force causing deformation has been released. — MS-10, p. 11 — Examples: The PL Test w/crumbling thread

e. Permeability means the ease or difficulty with which water will flow through a soil. — MS-10, p. 11

9. Exploration and Sampling

a. Purpose - To determine subsurface soil conditions and secure samples to evaluate the engineering properties so that a satisfactory foundation can be designed. — Soils Man. Ch. III, Earth Man. Ch. II

b. Test Borings - Subsurface exploration is accomplished by the drilling of holes called "test borings." Test borings are usually carried to a depth of 1½ times the minimum width of the planned construction. At this depth the influence of the proposed construction would be negligible, unless latent soil conditions are encountered, as in the case found in tide land areas. Test borings in these locations are carried well into the firmer soils, regardless of depth.

c. Drilling Equipment — Earth Manual p. 139 - 147

(1) Post hole auger or Iwan

(2) Augers

20981

(3) Bucket

(4) Rotary Wash

(5) Others

d. <u>Sampling</u> - Samples are obtained from each soil strata encountered for observation and/or laboratory testing

(1) Disturbed

(2) Undisturbed

(3) Standard Penetration Test

(4) N Values

Earth Manual
p. 574 - 577

20982

UNIT IV - SOIL FUNDAMENTALS

B. Physical Analysis & Testing

1. Laboratory Classification Tests

a. Sieve

(1) Dry — MS-10 Appendix A, p. 189

(2) Wet — AASHO - T11

b. Atterberg Limits — Hough p. 43 - 47

(1) Liquid Limit — AASHO T89-60 (MS-10)

(a) Moisture contents above this limit make the soil behave as a liquid

(2) Plastic Limit — AASHO T90-56 (MS-10)

(a) Moisture contents between the LL & PL define the plastic range

(3) Shrinkage Limit — ASTM D427-61

(a) Moisture contents between the PL & SL define the semi-solid range — AASHO T92-60

(4) Plasticity Index — AASHO T91-54 (MS-10)

(a) LL - PL = PI

2. Field Classification Tests — MS-10, p. 73-76

a. Sand & Gravel - visual examination of sizes. Gravel sizes run from 3 inches to the No. 4 sieve (3/16 inch); coarse gravel 3 inches to 3/4 inch; fine gravel 3/4 inch to No. 4 sieve. Sand sizes run from #4 sieve to No. 200 sieve (the smallest size particle that can be seen by the unaided eye); coarse sand No. 4 to No. 10 sieve; — Earth Manual, p 15-17

20983

medium sand No. 10 to No. 40 sieve; and fine sand No. 40 to No. 200 sieve.

b. Silt & Clay - classified by physical behavior - clays having cohesion and silts acting granular. Over a large range of moisture contents, clays exhibit considerable cohesion and can be rolled into a thread of approximately 1/8 inch diameter. Silts, lacking in tensile strength, will break apart and feel gritty in the hand. On drying, clays will harden and have a high dry strength, while silts will tend to crumble under applied pressure when dry.

c. Organic Soils can be distinguished by the odor and/or presence of decayed vegetation, usually in fibrous form. Organic soils are usually dark in color - either brown, gray or black. The application of heat to these soils will bring out their odor stronger.

3. Hydraulic and Mechanical Property Tests

PCA Soil Primer
Chapter 3

Earth Manual p. 37-69

a. Moisture Density - The density of a soil is its weight in a unit volume and is usually expressed in pounds per cubic foot. The moisture content of a soil is the percentage of moisture by weight to the dry weight of soil.

b. Consolidation - This test determines the compressibility of the soil under given loads. Consolidation is the squeezing out of water from a soil mass by externally applied pressure. Generally, this is a slow process consuming

Example: A 1-inch-high soil specimen consolidated 1/10 of an inch under 2000 pounds per square foot loading.

much time. In simplicity, the test is run by applying an external load on a soil specimen of given height and the deflection recorded by means of gages.

A 10-ft.-thick strata of the soil under 2000# per sq. ft. would therefore settle 10% (1/10 of 1 inch = 10%) or 1 foot.

c. Shear - These tests determine the strength characteristics of soil (cohesion and/or angle of Internal Friction.

(1) Direct Shear - The test consists of forcing a portion on the soil to slide over itself under a pressure or surcharge. The soil to be tested is placed in a split mold, one end fixed, and the force necessary to move the other section of the mold recorded until failure occurs.

(2) Unconfined Compression - In this test a sample of soil is subjected to a vertical axial force until the specimen fails along a shear plane or by bulging. The shearing strength is assumed to be half of the compressive strength.

(3) Triaxial Shear - This test is similar to the unconfined test except that a constant laterial pressure is applied during the test.

20985

Several tests at different lateral pressures can be run to develop the cohesion and angle values.

d. Permeability - These tests determine the ability of soils to transport water. In the laboratory two basic permeability tests are used - the falling-head permeater or the constant-head permeater. The constant head permeameter, as the name implies, maintains a constant height of water above the sample and is used on the more permeable soils - sands and gravel. The falling-head permeameter is used on soils of low permeability - clays and silts - where a wide range of values can be obtained because of the different head heights.

e. Expansion Test - As the fine grain soils tend to change in volume with change in moisture content, expansion tests were developed, in order to evaluate the expansive characteristics. Generally, these tests are run on soil specimens in fixed diameter containers. The soil is subject to saturation and the change in height is recorded and converted to a percentage. Soil having a volume change of over 5% is generally avoided in earth work. It is not too uncommon for some clays to have up to a 40% volume change from an oven-dry to a saturated state.

20986

B. Food Chemistry

Essential learning (Skill and knowledge)	Scope of instruction (Suggested content)	Information (Technical and related)
To understand scientific principles involved in food preparation	Basic food chemistry Changes in food due to: Cooking Freezing Curing Dehydrating Composition of foods: Elements Compounds Identification of foods and detection of adulterants Food spoilage: Causes Prevention Chemistry involved Food preservation: Chemical and physical changes	Practical demonstrations: Pasteurization Homogenization Litmus test for acidity

Suggested teaching materials: See items 13, 24, 37, 44 in appendix B.

2074

3.

f. Tests for Pavement Subgrades

(1) California Bearing Ratio (CBR) — MS-10, Ch. VIII

(a) The load (psi) to force a piston into a soil to a certain depth, expressed as a percentage of the load (psi) to force the piston into a standard sample of crushed stone.

(b) Used with emperical curves to design asphalt pavements.

(c) Used as a quality index of a soil to be used in a pavement structure or pavement foundation (basement soil)

(2) Resistance Value (R-Value) — MS-10, Ch. X

(a) Type of Triaxial Shear Test — Test Method No. Calif. 301

(b) The ratio of a given applied unit compressive stress to the transmitted lateral pressure is used to determine an index (0 to 100) of the ability of the soil to resist deformation. This is called an R-Value. — Since this test is widely used in Calif., students may wish to visit one of the Highway Labs near the school.

(c) The R-value varies with moisture and density, therefore, the R-value must be determined at the expected field conditions to be of significance in a pavement design procedure.

(3) Plate Bearing (K-Value) — MS-10, Ch. IX

(a) Similar to a CBR using 12 to 30" plates in the field.

20987

(b) To be effective for design, the materials tested (subgrade) must be at the same density and moisture as they will be under the pavement.

(c) Can be used to evaluate the strength of an existing pavement.

(4) Other California Subgrade Tests

(a) Specific Gravity

(b) Moisture - Density

(c) Expansion Tests

Calif. Materials Manual - Part I 200 & 300 Series

by Peck, Hanson &
Thornburg, Ch. 8,9 & 10

a. Foundations - There are many factors determining the type of foundation to be employed for a given structure. The nature of the structure, loads to be carried, subsurface conditions, and relative costs must be considered in the choice of a foundation. Foundations can be divided into two types - shallow (spread footings, rafts & mats) and deep (piles, piers & caissons). In choosing a foundation, all types should be

20989

considered. With the many factors involved, there are usually several acceptable solutions to each foundation problem. The final design is a balance of performance and cost.

b. Bearing Capacity - One condition the foundation must satisfy is bearing. From the shear test data obtained in the laboratory, the bearing capacity of the soil is computed. Roughly, the bearing capacity is 3 times the shearing strength. Other factors - size, type of footing, etc., will tend to increase this factor. In general, a factor of safety of 3 is used and in no case less than 2 in the final design.

Opt. Ref. Foundation Engrng. Ch. 13

c. Settlement - Another condition the foundation must satisfy is one of settlement. Generally, differential settlement within the structure is of more concern than a uniform settlement. While the whole structure could settle a few feet without damage, a differential settlement of 3/4 inch could crack the structure. The type of construction is considered in settlement studies. A concrete building is usually limited to a maximum differential settlement between adjacent columns of 3/4 inch, a steel structure, slightly more. Other factors involved are settlement time rates. On sand, as much as 75% of the settlement could occur upon application of load (during construction), while on some clays the settlement would not appreciably begin until after the structure is completed. Because of this, slightly more settlement is tolerable on sandy sites.

Earth Manual; p. 217-218

20990

3. Pavement Studies

a. Foundations

(1) Pavements are generally light structures with intermittant loads, therefore, except for heavy fill foundations and swampy areas, exploration is limited to 3 to 6' below finished grade.

(2) One purpose of the study, is to determine the quality of materials in cuts which are generally used in fills.

(3) Determine the strength of the materials directly under the structural section (basement soil or subgrade). In California we generally use the R-Value for highways or K-Value and CBR for airports.

(4) Sometimes the data are shown in a soil profile. Different soils are identified by a classification system, i.e., AASHO, FAA, Unified, etc.

Show soil profile

b. Structural Sections of Pavements

(1) The structural section is that portion above the prepared subgrade. Usually made of imported materials.

(2) Will be considering only light traffic pavements - heavy duty pavements are similar, however, have greater depth and more strict quality requirements.

298

056 238

MICROCOPY RESOLUTION TEST CHART
NATIONAL BUREAU OF STANDARDS-1963-A

(3) Will be covered in detail in Structural Series 2 for both flexible and rigid pavements.

4. Retaining Walls and Slopes

Opt. Ref. Foundation Engineering, Ch. 11

a. Design of retaining walls besides having to satisfy conditions of bearing in the foundation, also must resist lateral pressure. There are two extreme conditions of lateral pressure, that of active pressure and passive pressure. The active state occurs when all of the shearing strength of the soil is fully mobilized and the passive state occurs when the soil's strength is overcome in a backward direction. An at-rest condition falls between these two extremes and occurs on an unyielding wall when none of the soil's shearing strength is employed. Retaining walls are designed for conditions falling somewhere in between the two states, usually between the at-rest and active conditions. After the lateral pressures of the soil to be retained are known, an equivalent unit fluid pressure approximating the lateral pressure is employed in the design.

b. Backfills play an important part in the design of the retaining wall. Granular backfills are preferred as the active condition is more fully mobilized than with the fine grain soils. Clay

297

EBOS 20992

will reach an active state; however, slow continued yielding will cause the clay to lose its mobilized shearing strength. This increases the pressure on the wall until, if not adequately designed, a failure of the walls occurs. A clay backfill should not be used on a wall designed for granular soils. Another important consideration is preventing hydrostatic pressure build-up. This is accomplished by providing backdrains and/or weep holes.

c. Constructed slopes are based on type of soil, climatic conditions, height of slope, and the seriousness of a possible failure. Permanent slopes are designed for a safety factor of usually 3 and not less than 2. In sandy soils this is a slope of about 1 vertical to 1½ horizontal or flatter. In clayey soils the safe slope is a function of the height. Temporary slopes are constructed steeper and preferably in the dry months. Surface protection is provided by planting, matting, etc. Analyses of slopes are made several ways. One common method is to assume a failure circle in the slope and compute the forces resisting sliding and the forces that tend to slide. The critical circle is the one where the forces resisting are a minimum and the forces

Earth Manual, p. 213-216

that tend to slide are at a maximum. The factor of safety is computed by dividing the forces resisting by the forces tending to slide.

5. Drainage Studies

a. Surface

(1) A building project will normally disturb the site thereby changing the surface drainage patterns which previously existed,

(a) Change grades

(b) Change materials which will change absorption of the surface and the speed of runoff of precipitation.

(2) The engineer must design a drainage system to prevent damage to both on site and off site facilities. The system may contain:

(a) Eave troughs

(b) Down spouts

(c) Catch basins

(d) Trenchs

(e) Underground storm drains

(3) Because the drainage facilities are designed as a system - no changes to grades, pipe sizes or tyes, etc. may be made without a possible unbalancing of the system. Proposed changes <u>must</u> be referred to the designer.

Note to Instructor:

(1) You may wish to explain briefly Q = CIA the rational method of estimating peak runoff. See "Water Supply Engineering" by Babbitt & Doland as one reference.

Students do not need to study the problem in detail.

(2) The Asphalt Institute has published a manual "Drainage of Asphalt Paving Structure" (MS-15), which is now available.

20994

b. Subsurface

(1) Subsurface moisture affects the strength of most foundation soils.

(2) Subsurface moisture which enters and exists from a site may be disturbed by the facilities being constructed. It is therefore necessary for the designer to prevent buildup of moisture under buildings or pavements. To accomplish this, he may design special facilities to handle underground water. These may take the form of cutoff trenches, filter drains, etc.

(3) Inasmuch as the designer's information of subsurface conditions may be limited to a few borings during a dry period, you may help him considerably by calling his attention to conditions exposed by excavations during construction. This may give him the opportunity to improve his underground drainage system. Particular attention to water seeps.

(4) We must keep in mind that the same things that apply to surface systems apply to subsurface systems. Careful attention to design details during construction will bear heavily on its successful operation.

C. Hygiene and Sanitation

Essential learning (Skill and knowledge)	Scope of instruction (Suggested content)	Information (Technical and related)
To understand the importance of good personal hygiene	Basic principles of hygiene and their application to health	Diseases Parasitic infections Carriers Prevention of disease Characteristics of bacteria
	Bacteria: How bacteria may enter food Conditions needed for growth	
	Health habits: Rest Exercise Posture Recreation	
	Grooming: Hair care Teeth Skin Hands Feet Bathing Clothing	 Hair nets, caps Proper brushing habits Nails, nail polish Shoes, hose Uniforms
To know importance of sanitation	State and local sanitation laws	Laws relating to personal health
	Storing food: Raw Cooked	Types of refrigeration: Temperature Control
	Storing dry materials: Flour Meal Sugar	Bins, shelves, racks, containers
To know proper housekeeping procedures	Disposing of garbage and refuse material	Equipment
	Cleaning and care of all types of kitchen equipment	Detergents Sanitizing agents Purification agents
	Cleaning and maintenance of floors and work areas	
	Preventing rodents and insects	Insecticides Safety Other precautions
	Detecting presence of rodents and insects	
	Controlling rodents and insects	

Suggested teaching materials: See items 9, 18, 19, 25, 30, 50, 53, 59, 62, 72, 83, 88, 89, 92, 103 in appendix B.

2074

2075

(a) Gradation of aggregates in filters and drains, pipe sizes, etc.

(b) No interruptions to system continuity by placing blocks in way.

6. Dams and Other Large Earthwork

Earth Manual, p. 229-234

Usually large earthworks are undertaken by governmental agencies. Many complex factors are involved and all must be considered in the development of large earthworks. The purpose of the development, as an earthfill dam, for example, must consider location, power development, irrigation and runoff distribution, flood control, wild life, and many other factors. Once the feasibility is established, a series of investigations are run until a site is selected. Following site selection, a more fully subsurface investigation is carried out and design of the structure is started. Usually several preliminary designs and cost estimates are made up from which a final design will be developed. In the case of earthfilled dams, the design must satisfy the following conditions: The foundation must be adequate to hold the embankment, relatively impervious, sloped sufficiently under all weather and reservoir conditions to prevent sliding, protected against wave action and erosion, and overturning. Riprap employed on the surface to prevent

20996

erosion from wave action must be protected from infiltration by the impervious core by designed "blankets" of selected material, sized between the two different materials. This is called a Zoned Embankment, and is the type generally used in earthfilled dam construction. Other large earthworks include canals, channel, bridges, tide-land filling, and piers and wharfs. Each has its own soil and water problems; however, are handled in a similar manner as discussed above.

7. Shoring and Underpinning

Opt. Ref.
Foundation Engineering. Ch. 12.

In the construction of subsurface structures, shoring is usually required during excavation and construction. Shoring consists of placing a temporary system of braces to retain the soil around the construction. The design of shoring is similar to that of retaining walls; however, the material employed is generally not of permanent nature; that is, subject to rot and/or rust. One generally accepted method is to install first, vertical soldier beams, and then horizontal lagging as the excavation progresses. In some instances, where the excavation is deep, struts placed against the beams are employed; or a newer method is that of tying the beam into the retained soil by means of a prestress anchor system called tie backs. Where an excavation is adjacent to an existing structure, it

20997

may be necessary to underpin the existing structure. The simplest method is to replace the existing foundation with a deeper one which then keeps the foundation pressure off the shoring. Underpinning is also employed in correcting inadequate foundations and often is expensive due to the working space restrictions.

20998

D. Use and Control of Soil Materials

1. Compaction

Hough - Chap. 14

Earth Manual
P. 192 - 211
P. 237 - 254

a. Purpose

(1) To densify the soil (reducing its volume) thereby increasing its strength by developing particle to particle contact.

(2) To decrease permeability

b. Principles and Methods

(1) Compaction is the volume change produced artificially by momentary load application such as rolling, tamping or vibration.

(2) Methods used are mechanical, vibration, jetting and other special methods.

c. Compaction Tests

(1) AASHO, ASTM and Calif.

(a) These are relative compaction test methods.

See Appendix A in A.I. Soils Manual for AASHO & ASTM and State of Calif. Materials Manual

(b) Compare in-place density with a laboratory density where the sample is compacted by a standard weight in a standard mold at optimum moisture content.

(c) Mold sizes and laboratory compaction efforts are different for the different methods

20999

(2) Others

(a) Proctor Needle is a penetrometer type of instrument. Measures the soils resistance to entry.

(b) Nuclear methods. Radioactive source is placed on or in the soil and the density is measured by special instruments. Specially trained technicians are required for this work.

d. Laboratory acceptance and control tests

(1) Acceptance tests will usually be gradation, plasticity, etc.

(2) Laboratory control tests as concerns compaction involve moisture-density relationships and determining a reference standard for field control tests.

(3) Sampling is most important. The material must be representative.

e. Field control tests

(1) Proctor Needle — Calibration ASTM D 1558-58T

(2) Sand-Volume. Carefully pour calibrated sand into a hole to determine the volume of the material removed. Part of the In-Place density test. — ASTM D 1556 - 58T

21000

(3) In-Place density. Comparison of the field density with lab density to determine relative compaction.

(4) Moisture content of soil

(5) Counting number of passes by rollers to see specifications are being met. (Many specs are written this way to eliminate necessity of expensive testing).

f. Compaction Equipment and Uses

(1) Sheepsfoot

(2) Vibratory Rollers and Tampers

(3) Grid Roller

(4) Pneumatic rollers

(5) Steel Wheel Rollers

(6) Construction Equipment

(a) Hauling trucks

(b) Graders

(c) Scrapers

(d) Tractors

(7) Hand operated

(a) Tampers - hand and pneumatic

(b) Vibratory compactors - Wacher, Barco, etc.

Hough - Chap. 14 has good discussion on each type, its advantages and the type soils where effective.

Instructor and students may obtain data from equipment dealers or manufacturers for each piece of equipment.

g. Compactive Effort

(1) Mechanical means consists of compressing the soil into a dense

Hough - Chap. 14

SOOLS 21001

state by applying weight. The end results depend on the size of lifts, moisture content, number of passes and weight of equipment.

(2) Jetting consists of forcing water thru the soil. This method can only be used on highly permeable material (clean sands and gravels) with a system to drain off the water. The water forces the grains to interlock better, thus reducing the voids.

(3) Special Methods include blasting with resulting shock waves, driving displacement piles, and a process of creating sand piles by jetting called Vibro flotation. The first two methods above are usually expensive.

2. Chemical Stabilization

PCA Soil-Cement Handbook

a. Principles and Methods - Chemical stabilization is used to improve certain properties and/or reduce undesirable ones. By adding a small quantity of chemical to a soil the bearing capacity can be increased, the expansion characteristics reduced, and/or frost heave prevented. The process involves adding the chemical and mixing it with the soil before compaction takes place.

Bros Handbook of In-Place Soil Stabilization

b. Cement added to soil increases the bearing capacity and reduces permeability. A soil-cement is a hardened material containing about 12% cement by weight. A cement modified soil is a material of less hardness employing about 4% cement by weight. This treatment is used where strength is not the required object, but some other characteristic of the soil requires changing.

c. Chemicals employed in chemical stabilization are lime to reduce expansion, salt or sodium chloride to prevent frost heave, or lime rock to increase strength. Also, many other chemicals are presently being tried.

3. Physical Stabilization

a. Asphalt Mixtures

(1) Asphalt coats each particle and provides cohesion. This prevents loss of density, therefore, loss of strength.

b. Crushing aggregates

(1) Crushing generally makes the surface texture rough, making it more difficult for one particle to slide past the other.

c. Aggregate blending

(1) Blends to improve gradation and improve stability are often made in road work. Gradation may be improved by blending to supply missing sizes and stability improved by providing rougher texture and more contact points within the compacted mass.

GOOJS 21004

E. Construction and Inspection of Earthwork

Earth Manual, P. 183, 184

1. Grading plans and specifications - The purpose or intent of grading plans and specifications is the development and completion of a final product which will meet the engineered requirements of the proposed construction. Plans can be divided into two categories - one specifying the engineering properties to be met, the other specifying the method and equipment to be used. In excavating, the intent is that an objectional material be removed and/or that a sufficient engineered fill can be developed and/or the new grades are lower. In the field it is important that this intent be met, even if the scope of the plans does not cover a given situation. This is done by change order to the plans. (A good base must be provided in order to compact the engineered fill properly.) In filling, a certain thickness of lift is usually specified in order that the required compaction can be met. The compaction test method must be specified along with what material may be used, including maximum rock size. Testing requirements and the method of correcting defective work should be included.

21005

Area III

MATHEMATICS RELATED TO FOOD PREPARATION

Area III has as its objective the development of the student's understanding of the mathematical background required to intelligently perform the varied tasks associated with food production and service. Instructors should help students develop an awareness of the importance of mathematics in the construction of formulas. The student should understand the necessity of accuracy in calculating ingredient amounts when reducing or increasing a formula.

The student should know that all controls—and formulas (recipes) are controls—depend on accuracy if they are to be effective. A knowledge of weights, measures, degrees of temperature, and percentages is essential. Purchasing requires a knowledge of arithmetic in order to calculate discounts for comparative purposes. Calculation of food costs, labor costs, and menu prices requires knowledge of addition, subtraction, multiplication, and division.

The outline gives the minimum essentials only; greater emphasis is not only desirable but recommended.

Essential Mathematics

Essential learning (Skill and knowledge)	Scope of instruction (Suggested content)	Information (Technical and related)
To master basic mathematical skills	Fundamental mathematical processes:	Weights and measures
	Addition	
	Subtraction	Use of scales
	Multiplication	
	Division	Use of oven and meat thermometers
	Fractions	
	Decimals	
	Percentages	Recipe calculation:
	Weights	Increasing
	Measures:	Decreasing
	Liquid	
	Dry	Steam and other pressure gauges
	Degrees	
To calculate costs	Calculation of raw food costs	Standard or accepted weights or measures of various servings
	Calculation of portion costs or cost per serving (Ready-to-serve cost)	Food Labor cost Overhead cost
To control kitchen costs	Maintenance of records necessary for adequate control cost within the kitchen	

Suggested teaching materials: See items 3, 28, 41, 52, 80 in appendix B.

2076

Existing grades, along with the planned new grades, should be clearly shown, including tolerances on finished grades.

2. General Grading and Filling

Earth Manual, P. 209 - 211

a. Excavating can be accomplished by many means, the method determined by the equipment available, type of material to be excavated, size of job, and access. Equipment includes loaders, rubber-tired or crawler type, shovels, drag lines, scrapper, and conveyors and hoppers. If the excavated material is to be employed in engineered fills, the area should first be cleared of surface vegetation and other deleterious materials. Also, the moisture content should be determined in order to bring the material to optimum for compaction. During the excavating work it is essential that a homogeneous consistency be maintained; that is, no rock or fines be allowed to occur. This is done by excavation from the bottom up (in the case of a bank) with each bucket load, rather than cutting down in horizontal layers. (Banks should be cut into on a slight angle rather than perpendicular to the face. This will yield larger loads and less wear on the

21006

passes required to meet the specifications should be determined with the equipment employed. This helps in establishing the criteria for the balance of the job. Prior to starting the fill, a firm base should be provided or provision be made to build up one. Fill cannot be compacted satisfactorily on a weak base. The equipment employed in the compaction work should be suited to the material. Many times two types of compaction equipment are employed and on occasion this will result in the equipment working against each other. An example would be where a flat-wheeled roller was used to compact the surface, followed by the sheepsfoot roller which tends to compact the lower lift. In this case all the sheepsfoot roller would be doing is destroying the crust left by the flat-wheeled roller. The fill should be placed on a level plane to receive uniform compaction and should be sloped slightly during the rainy season to help drainage.

3. Offshore Grading and Filling

a. Excavating under water usually is to remove poor soils or to increase the depth of water for ships. Excavating offshore areas takes

21008

on many forms, from channel clearing to dredging mud flats. The normal method for excavating under water is by dredging. Dredging can be done with a clam shell, dragline or dredge. A dredge works similarly to a vacuum cleaner. in that it sucks up the material and then carries it by pipes away from the areas. Another method of excavating mud is by displacement. A fill is placed concentrated on an area causing the mud to flow. This is called a mud wave.

In excavating near wharves or other structures not only must care be exercised against undermining but consideration must be given to existing wood piling. In many cases the wood is protected only to a nominal depth into the mud and a lowering of this mud would cause the piling to rot out of this point.

b. Filling in water presents many problems. Most materials cannot be compacted under water. Clays and silts become saturated and mushy, while the granular soils are less affected by the water. The standard method is either to dump rock, gravel or sand into the water or by pumping a sand slurry into the area to be filled. As discussed under

21009

Excavation it is sometimes possible to excavate a mud and fill concurrently by filling in a concentrated area and causing a mud wave. In this method, the fill is brought to grade at a point and worked outward over the planned area to be filled. However, in most cases a mud wave is to be avoided. This is accomplished by filling the site evenly, a lift at a time covering the entire area, and employing light equipment. Problems occurring in tideland filling is that of the existing ground, usually an old fill consisting of debris and garbage. Many tideland areas have long been used as dumps. This, coupled with the underlying mud, causes many settlement problems in reclaimed land. Fills adjacent to open waters also have to be protected from wave action. This is done by placing, what is called, riprap on the slope. Riprap runs from rocks weighing up to 20 tons down to 6 inches in diameter. These rocks tend to break up the force of the wave and prevent erosion. If the fill is fine grain, a filter blanket is provided between the fill and the riprap to prevent infiltration of the two materials. A filter material is a

21010

designed graded material with sizes between the two extreme sized materials.

4. Material Sampling

a. Material sampling in construction is a highly important item. Usually some 100 pounds of a proposed material, be it fill, rock or aggregate, is secured for approval. The problem is securing a sample that represents the material sampled and not an off-graded portion of it. In stockpiles the larger size will tend to collect along the outside bottom edge, the wind will blow the fines to the downward side. It can be seen that obtaining a sample at one point in the stockpile will not give a representative sample of same. In a bank the material at the crown will be slightly different than at the toe (soil usually is uniform horizontally for short distances). In securing a sample one must take portions of the material from as many points as practical, not only at the surface but in the material as well. Secure the most representative sample, that is, not what looks good or bad, but that which is a cross section of the material.

21011

If need be, take two or more samples if there is a large variance in the material. Mark on the container the source of the material, date of sampling, by whom, and intended use of the material. If the material is not going to the laboratory immediately, try to enclose a portion of the material in a waterproof container so that an in-place moisture content can be obtained.

5. Drainage - Surface and Subsurface — Earth Manual, P. 214-215

   a. Surface - to provide runoff — Opt. Ref. Foundation Engineering, P. 151-156

UNIT IV - SOIL FUNDAMENTALS

Teaching Outline	Techniques, Aids, Devices and References
F. Construction and Inspection of Earthwork (continued)	
1. Foundation Plans and Specifications	Earth Manual
a. Purpose. To provide a clear and precise plan of the foundation elements	P. 310-321
b. General - The plans should include footing size, elevation of bottom, unit loading, soil expected, reinforcement and other relative data.	
2. Installation of Structural Foundations	
a. Shallow	
(1) Machine excavation - Backhoes, trenching machines, Gradalls	
(2) Type of pours - neat or formed. Backfill required for formed pours.	
b. Deep	Opt. Ref. Foundation Engineering, Ch. 9 and 10
(1) Pile Driving - piles	
(2) Drilling - Belled caissons, piers	
c. Special	
d. Load Tests	
(1) Shallow footings	
(2) Piles	
3. Installation of Floor Slabs on Grade	
a. Subgrade preparation	
b. Moisture barriers - base work	
c. Waterproofing	

21014

4. Paving Plans and Specifications

a. Plans

(1) Plan view will generally show site with paved areas outlined, elevations and details of drainage installations, pavement cross sections, curb and gutter, etc. This is dimensional information.

(2) Small jobs (schools, etc.) will generally have one sheet for this.

(3) Highway plans will generally have several sheets of plans and profiles of the roadbed in addition to detail sheets.

Note to Instructor:

Obtain typical examples and make transparencies to project on screen to show the information.

b. Specifications

(1) Specifications outline the materials requirements.

(a) Quality of materials and types (grade of asphalts, etc.)

(b) Compaction requirements

(c) Equipment requirements

(d) Methods to be employed in construction.

(e) How quantities are measured for payment and how payment is to be made.

Note to Instructor:

Most paving in Calif. is done under Standard Specifications for the Div. of Highways. Obtainable from any Highway office. You can point out details from this publication.to the student, such as gradation of base courses, crushing requirements,etc.

There are 3 sessions on pavement in the next course (Structural Series #2) for more detail on placement, etc.

21015

Area IV

ENGLISH RELATED TO FOOD PREPARATION

Communication skills play an important role in food production and service. Area IV outlines the basic essentials of effective communication. Basic grammar should be stressed. It is essential that the student become familiar with the language of the trade. The instructor should acquaint the student with the meaning and correct use of cooking and menu terms, with the writing of menus, and with the sequence of items on menus.

The student who wishes to prepare for a career in the food industry must develop the ability to express himself adequately and correctly. Letters, orders, directives, and reports become very important as the food worker advances to positions of greater responsibility.

Basic Essentials of Effective Communication

Essential learning (Skill and knowledge)	Scope of instruction (Suggested content)	Information (Technical and related)
To know proper expression	Fundamental principles and rules of oral and written expression:	
	Letters	
	Reports	
	Instructions	
To know shop or trade vocabulary	Terminology for kitchen equipment such as:	Pronunciation, spelling, meaning
	Walk-ins	
	Trunnion kettles	
	Rotary ovens	
	Terminology used to describe utensils and tools	Pronunciation, spelling, meaning
	Terminology for cooking and baking operations:	Pronunciation, spelling, meaning
	Basting	
	Marinating	
	Blanching	
	Proofing	
	Terminology for stations or work operations	Pronunciation, spelling, meaning
To know how to plan menus	Basic factors to consider in menu planning:	
	Refrigeration	Left-overs
	Market	Availability of products
	Season or time of year	Foods that fit season or holiday
	Clientele	Age, income, sex, occupation
	Kitchen	Equipment, employee skills
	Time of day	Breakfast, lunch, dinner
	Appearance	Contrast, color, plate topography
	Dining area:	
	Tables	Top size
	Booths	Type of service
	Counter	Space

2077

(2) Specification requirements may be spelled out in the job specifications or included by reference to a Standard Specification, such as the Standard Specifications for the California Division of Highways. The current issue is dated July 1964.

5. Retaining Wall Construction
   a. Excavating - Precautions
   b. Backfilling - Materials, methods, Wall bracing and curing, drains
6. Inspection Procedure and Techniques
   a. Check - elevations, locations, soil conditions, reinforcement, disturbed bottoms, plumbness and caving in deep foundations, etc.
7. Safety
   a. Equipment working order, backup bells, traffic control
   b. Shoring
   c. Miscellaneous
8. General Codes and Specifications
   a. Uniform Building Code
   b. California Title 21
   c. California Standard Specifications (Div. of Highways)
   d. Local Building Codes

21016

APPENDIX - SOILS

General Information and History of Soil Mechanics

"Soil Mechanics" is a relatively recent term applied to the science of soil engineering which in itself is based on theories developed over many years. "Soil Mechanics" is defined as the application of known mechanics and hydraulics to engineering situations relating to soils.

Early studies of soil were persued in the 18th and 19th century by Coulomb and Rankine. They were recognized as the first to attempt to apply mathematical theory to soil reactions. The theories developed by these men are still forming the basis for modern methods of computing earth pressure.

Charles Augustin Coulomb (1736-1806) was a French military engineer prior to his retirement in 1789 because of poor health. In the period from 1789 until his death he devoted his efforts entirely to scientific research, a part of which was related to the mathematical solutions of soil failure. He was better known for his theories on friction, tension and electricity.

William John Rankine (1820-1872) was a Scottish civil engineer and physicist. He wrote many authorative papers on civil engineering and thermodynamics.

Scientific studies of soils have greatly increased in the last 40 years. An international conference on Soil Mechanics was held at Harvard University in 1936, which resulted in stimulating interest and may be considered as a landmark in present development. This conference was held again in 1948 and in 1953.

The very early studies related to cohesionless soils such as sand, in 1914 cohesion of soils was scientifically explored. In 1925 important studies were made in relation to the consolidation of soil.

Progress in soil studies were promoted to a great extent by the development of automobiles and airplanes, both of which, due to speed and loads, made existing methods of road building inadequate. The greatest period of advancement was during World War II when airfields were built in many parts of the world.

Early tests for measurement of shear in soil was developed originally about 1885. Many attempts have been made to develop reliable statistics for each type of soil. Most of these theories have been discarded for the standard laboratory tests and on the site tests presently used.

Dr. Karl Terzaghi wrote a publication entitled "Theoratical Soil Mechanics" in 1943. It has done much to consolidate known principles and create interest, which has resulted in many recent publications on the subject.

The texts used in this course have been developed quite recently and are usable working manuals of modern practice. If the student is desirous of expanding his knowledge in this area, he will find ample opportunity by studying the many publications available at our larger public and college libraries.

21017

BASIC SOIL DEFINITIONS

ADOBE
An alluvial playa clay, subject to large volume change with change in moisture content.

ALLUVIAL
Soil that has been deposited by the movement of water.

AZONIAL
Not restricted to any particular region; having no character or structural arrangement.

BARROW
To import soil from off-site for the purpose of forming elevations of structural soils.

BARROW PIT
The location from which imported soil is obtained.

BEAR
To support or hold up, passively or in passive form.

BINDER
Small particles in a soil (generally a minus No. 200 s.s. material) having the ability to hold together other and larger particles.

BLEND
To thoroughly fuse material of different gradation with each other.

BOULDER
Any rock, three inches or more in diameter, which has been moved from its original location or from its parent formation.

CAPILLARITY
The action by which a liquid rises in any direction above the horizontal plane of a supply of free water.

CLAY
A fine-grained earth, chiefly silica, but containing enough aluminum to make it plastic and cohesive.

COBBLES
Small boulders which have been worn smooth by the action of water and movement.

COEFFICIENT
A factor that contributes to produce a result.

COHESION
The mutual attraction of the particles of a soil to each other in the presence of moisture.

21018

COMPACT
To make more dense by compression; closely and firmly packed and fixed together. (Compactible soils do not rebound).

COMPRESS
To force or squeeze together; to make more compact by pressure. (Compressible soils can rebound).

COMPRESSIBILITY
A property of soil that causes it to rebound or to remain compressed after compaction.

DENSITY
The unit weight of a material to a given volumn.

DIATOMACEOUS
The siliceous remains or deposits of small marine live called diatoms.

DILATANCE
A characteristic of soil (silt) where surface moisture can be caused to recede by pressing the soil with the fingers.

ELASTICITY
The ability of a soil to rebound or retract after having been compressed or moved.

EXPANSIVE
To change volume with the change of moisture content.

FINES
The fine-grained particles in a soil mass. Usually designated as the percent of silt (M) and clay (C) in mass.

FLOURY
The fines whose structure is flat or flaky, rather than prismatic or granular.

FREE WATER
Water free to move downward by gravity, or disappear from evaporation.

FRIABLE
Easily crushed or crumbled into a powder.

GRADATION
The gradual change by steps or stages from one sieve size to another of the grain sizes of a soil.

GRANULAR
Soil whose molecules are prismatic, or grainy, or cubical in form.

GRAVEL
One of the four major divisions of soil, with an irregular surface, and sized between boulders and sand.

21049

GRAVITATIONAL

(Water) Water that is free to move downward and to drain from the soil by force of gravity.

HORIZON

Horizons are modified layers of soil, with particular characteristics, which form the profile of the earth.

IMPERVIOUS

Incapable of being penetrated by water.

IMPORT

To bring in from another site or location.

INTERNAL FRICTION

The resistance to the sliding of the particles of a soil by themselves within the mass.

INTRAZONAL

Soils with characteristics influenced by local factors, such as peat bogs, salt lakes, etc.

LIFT

To raise to a higher elevation by placing a quantity of soil upon the existing soil.

LINEAL CHANGE

An increase or decrease in one direction of the soil mass with the increase or decrease of the moisture content.

LIQUID LIMIT

The percentage of moisture content of the soil when it passes from a plastic to a liquid state.

LIQUID STATE

The percentage of moisture content of the soil when it passes from a plastic to a liquid state.

LIQUID STATE

When the moisture content is such that the soil flows easily and assumes the shape of its container.

LOAM

An even mixture of sand, silt and clay of different sizes.

LOESS

Wind born dust of variable composition found in dry continental areas.

MOISTURE

-The fluid (water) content suspended in the soil.

MOTHER

The origin or source of a soil; the "C" horizon of the earth's profile.

21020

NONPLASTIC
Silts and sands which contain no aluminum and cannot be rolled into 1/8th inch threads.

OPTIMUM
The best or most favorable degree or condition.

ORGANIC SOIL
Having to do with the fossils of organs, as: plant components, carbon compounds, etc.

PARENT MATERIAL
The mother material; the "C" horizon from which the "A" and "B" horizons are formed.

PEBBLES
Fragments of rocks, sized between boulders and sand (as gravel); worn smooth by water and motion.

PERMEABILITY
The property of a soil that allows it to transmit water.

PERVIOUS
Allowing passage through; same as permeable.

PLASTICITY
Material that, under certain conditions, can be influenced or molded into permanent shapes.

PROFILE (SOIL)
A vertical cross-section of the soil layers of the crust of the earth.

SAND
Loose, gritty particles of disintegrated rock.

SATURATION
Thoroughly soaked with moisture, completely wet.

SHEAR
The effect obtained when the external pressure upon a quantity of soil is greater than the internal resistance to that pressure.

SEPARATES
A name given to different sizes of soil and setting definite limits for the sizes of each.

SILT
A fine-grained, nonplastic earth, chiefly silica, but with little or no aluminum in the mass.

SOIL
The surface layer of the earth, composed of a disorganized mass of mineral particles, varying in shape, size and quantity.

21021

STRUCTURAL

The load-bearing value; the resistance to weight; the strength.

STRUCTURE

The shapes and sizes and quantities of the particles which make up the soil mass. The structure is indicative of the drainage characteristics of the soil.

SUBSOIL

The "B" horizon; usually structural soil.

SURFACE SOIL

The "A" horizon; usually organic in character, unstable, non-structural; the top-soil.

TEXTURE

The composition, or the amount of soil separates, in a soil mass. Greatly influences the feel of the soil in making field tests.

VOID-RATIO

The relation, prercentage-wise, between the volume of solid particles of a soil mass and the gaseous areas between the particles.

21023

CONCRETE USES

Plain concrete is defined as concrete containing no reinforcement. In addition to plain concrete, there are other types used widely for construction. This unit will cover some of these uses.

REINFORCED CONCRETE

Reinforced concrete is concrete containing reinforcement to increase its tensile strength. It is designed on the assumption that the two materials (concrete and reinforcement) act together in resisting forces.

Reinforcement is the term used to describe the steel bars or welded wire fabric (wire mesh) placed in concrete to increase its tensile strength. Concrete is very strong in compression--that is, very strong for supporting loads that are placed directly upon it, but it sometimes requires steel reinforcement to help it resist stresses or forces that tend to bend or pull it apart.

PRESTRESSED CONCRETE

Prestressed concrete involves another concept. It, too, is generally applied to concrete members that are subjected to loads that cause bending, such as beams, girders, and slabs. The concrete is compressed by stretching steel wires through the member. In normal reinforced concrete, all tensile stresses are carried by reinforcing steel. In a prestressed member, the entire cross-section is effective in supporting loads.

Prestressed concrete has been used for highway and railroad bridges, industrial buildings, precast joists, pressure pipe, poles, piling, water tanks, roof systems, and many other purposes. The savings in materials made possible by prestressing is impressive. Up to 50 per cent of the concrete and 75 per cent of the steel used in a conventionally reinforced structure can be saved.

The prestressing force is applied by stretching the high-strength steel reinforcement. There are two general methods of doing this: pretensioning (before placing the concrete) and posttensioning (after the concrete has hardened).

In pretensioning, steel wire strand is stretched in the form prior to placing the concrete. Concrete is then cast and allowed to harden, after which the wires are released from the outside anchorage. As the wires contract, they transmit compressive stresses to the concrete by bond. Very-high-strength stranded-steel wires are used in pretensioning.

21024

In the posttensioning process, steel cables are located in ducts embedded in the concrete. The steel is stretched by hydraulic jacks after the concrete has hardened. The steel rods or cables are anchored to one end of the beam by mechanical means. Jacks are used to stretch the steel, which is then anchored at the other end by a mechanical anchor. Large-diameter rods or cables are used since the mechanical anchor holds the tension and it is not essential that the concrete be bonded to the steel.

PRECAST CONCRETE

Precast concrete has become popular because of the economy and quality control. When a large number of identical units are to be built, they may be precast on the job or at a specially equipped plant. By using assembly-line production methods, a considerable savings is realized, particularly in forming. Another advantage of precasting is that work can be done during slack periods and then stockpiled for later use. Components such as beams, girders, and columns are then available when needed.

Manufactured items such as concrete masonry, drain tile, concrete pipe, silo staves, and many other products are manufactured by large machines. These items are precast, of course, but are generally referred to as "concrete products." They are mass-produced.

LIGHTWEIGHT CONCRETE

Conventional concrete weighs on the average about 150 lb. per cubic foot. Lightweight concrete can be made either by using gas-generating chemicals or by the use of lightweight aggregates such as expanded shale, clay, and slag. Concretes containing aggregates such as perlite and vermiculite are very light in weight and are used primarily as an insulating material.

Lightweight concretes are sometimes classified according to the unit weight per cubic foot. These include:

1. Insulating lightweight concrete--unit weight of 20 to about 70 lb. per cubic foot and compressive strengths seldom exceeding 1,000 psi.

2. Structural lightweight concrete--unit weight up to 115 lb. per cubic foot and a 28-day compressive strength in excess of 2,000 psi.

3. Semi-lightweight concrete--unit weight of 115 to 130 lb. per cubic foot. Normal-weight sand is substituted as a partial or complete replacement for lightweight fine aggregate.

The first extensive use of lightweight concrete was for concrete block. Today, however, producers, contractors, and others are using lightweight concrete successfully for structural and insulation applications that include cast-in-place and precast walls, floors, roof sections, and for fireproofing.

2078

The general principles of normal-weight concrete proportioning may be applied to lightweight-aggregate concretes. When the aggregates are highly absorptive, however, some modifications are needed.

The uniformity and quality of lightweight concrete are dependent largely on the uniformity of moisture content of the aggregate. If moisture varies in aggregates at the time of batching, slump, yield, and uniformity may be difficult to control. The moisture content of the aggregate should be known and aggregate batch weights should be adjusted to compensate for changes in absorbed water. If the final quantity of water added to the mix produces less than the required slump, additional water may be added to satisfy the slump requirements.

To control the uniformity of lightweight concrete, the cement content, slump, and volume of dry aggregates per cubic yard of concrete should be kept constant. Unit weight tests of fresh concrete should be made frequently.

THIN SHELLS

Thin shells of concrete were first used in Europe in the early 1920's. In recent years, thin shells have become very popular in the United States. As the term implies, concrete is placed in thin sections--some as thin as 2-1/2 in. In many cases, even this thin cross-section is more than is needed to meet strength requirements. However, rigid building codes prescribe a minimum of cover that usually makes 2-1/2 in. the thinnest allowable cross-section in the United States. In Mexico, shells of 5/8 in. have been built.

Fig. 1. Shell action.

Shells derive their strength, and consequently part of their economy, from their shape. For example, hold a sheet of paper along one end and lift it

21026

from the table. It hangs limply from the points of support because it has practically no strength when cantilevered.

Roll the sheet into a semicircle and hold it along one edge. Now it will not only cantilever but will also support weights such as paper clips.

If we were to accordion-pleat our sheet of paper we would discover that its structural strength would be increased much in the same manner as when curved. The depth of the roof and the intersection of the folds explain the great spanning and load-carrying abilities of folded-plate shells.

The savings in materials for the roof, impressive though they are, are only one of the many economies in shell construction. Since considerable weight has been eliminated in the roof, the size of supporting columns and reinforcement can be reduced.

The economy of any shell roof is determined largely by the number of times that forms can be reused. Often forming costs can be reduced greatly by the use of mobile forms.

There are four commonly used types of shells--barrels, hyperbolic paraboloids, domes, and folded plates. Within each category there are many possible variations in shape.

Barrel shells are of two types--short and long barrels. Long barrels have short chord widths compared to the span between supporting ribs. Conversely, short barrels have large chord widths in proportion to the span between ribs.

Fig. 2. Long barrel shell.

Fig. 3. Short barrel shell.

21027

Fig. 4. Hyperbolic paraboloid saddle type.

Fig. 5. Hyperbolic paraboloid umbrella type.

The hyperbolic paraboloid is a shape of double curvature; that is, its surface is curved on two planes. Double curvature imparts improved stiffness to hyperbolic paraboloid shells and increases their ability to span and carry unsymmetrical loads. Two commonly used variations of the hyperbolic paraboloid shell are the saddle and umbrella shapes. Despite its double curvature, this shape is composed entirely of straight lines. Therefore, it is possible to build forms with straight lumber.

Fig. 6. Dome.

Dome shells are the aristocrats of roofs. (The dome is actually a portion of a sphere.) Their perfectly symmetrical shape and spacious, vaulted interiors are inspiring.

Fig. 7. Folded plate, V type.

There are three basic types of folded-plate shells--V-shaped, Z-shaped, and a modified W-shape. An example of the V-type is shown in Fig. 7.

21028

SHOTCRETE

Shotcrete is the term used to designate pneumatically applied portland cement plaster or concrete. A gun, operated by compressed air, is used to apply the cement, water, and aggregate mixture. The water may be added to the dry materials as they pass through the nozzle of the gun or as the materials are mixed.

When properly made and applied, shotcrete is an extremely strong, dense concrete and has high resistance to weathering. Absorption is low, making it an excellent waterproofing medium. Resistance to abrasion is comparable to that of quality cast-in-place concrete made from similar aggregates.

TILT-UP CONSTRUCTION

Tilt-up construction is a fast, economical way to build one-story buildings with concrete. The concrete walls of a tilt-up building are cast in sections or panels, flat on the floor or on a smooth bed of sand. After wall panels have been cured they are tilted to their vertical positions and fastened together to make a wall. Fastening of the wall panels into final position is accomplished by casting reinforced columns between them. These reinforced columns are cast on top of pier footings previously cast and extending into the ground, or on a continuous foundation. Reinforcing steel is continuous from the pier or foundation to the top of the column.

SANDWICH WALL

Sandwich wall panels are insulated concrete panels that are cast flat. They may be precast or site cast. A typical 6-in. wall panel would have a 1-1/2-in. section of expanded polystyrene between two 2-1/4-in. sections of concrete. Sandwich wall panels are lifted into vertical position and columns are cast much like tilt-up construction.

LIFT SLAB

Lift slab is a method of construction where the floor slabs of a building are cast on the ground, one on top of another. Then the slabs are jacked into place by means of hydraulic jacks and fastened to columns. Structures several stories high have been built by this method.

TEST OR DISCUSSION POINTS

1. Define reinforced concrete.
2. What is reinforcement and how is it used?
3. What is the difference between reinforced concrete and prestressed concrete?
4. What are the two general methods used for prestressing?
5. What materials savings are possible with prestressing?
6. Why is precast concrete popular?
7. Regular concrete weighs approximately 150 lb. per cubic foot. What is the weight limit for lightweight concrete?
8. Name the three types of lightweight concrete.
9. What are thin shells?
10. Name the four common types of shells.
11. Describe tilt-up construction.

APPLICATION

Discuss concrete uses.
Plan a field trip to view local examples of special concrete uses.
Visit a concrete products plant.
Show film Tilt-up Construction on the Farm. (See film list; also note other applicable films that can be used.)

Concrete has several unusual characteristics that make it a versatile and widely used construction material. New developments backed by years of research have provided today's concrete user with a unique, attractive, and practical product. Architects, engineers, and builders have used concrete with imagination and skill to create exciting and distinctive structures.

Freshly mixed concrete is a combination of inert materials (aggregates) and a paste composed of portland cement and water. The aggregates generally used are sand and either gravel or crushed stone. These, obviously, have no cementing value of their own; their function in concrete is to serve as a filler. The paste changes from a semi-fluid substance into a solid binder as a result of chemical reactions between water and the various compounds in the cement. The final quality of the concrete depends upon the effectiveness of the hardened paste in binding the aggregate particles together and in filling the voids between them.

PROPERTIES DESIRED IN FRESH OR PLASTIC CONCRETE

Although freshly mixed concrete is plastic only temporarily, certain properties are desired at this stage because they affect the quality and cost of

21031

hardened concrete. These properties, discussed in detail later, are defined as follows:

1. The "wetness" or "dryness" of the mix is referred to as the consistency or slump.

2. All concrete should be mixed thoroughly until it is uniform in appearance, with all ingredients uniformly distributed.

3. Workability is the ease with which concrete is placed and consolidated.

PROPERTIES DESIRED IN HARDENED CONCRETE

The properties desired in hardened concrete are durability, strength, watertightness, and resistance to abrasion. All of these are influenced by the quality of the portland cement paste. The relation between the amount of water and cement used in the paste is known as the water-cement ratio. The quality of the paste is determined by the total amount of water mixed with the cement. The paste can be compared to a powdered wood glue: mixed to the right consistency it will glue; add too much water and it will be seriously weakened. This is why concrete is commonly proportioned according to the amount of water to be mixed with each bag of cement. The quality of the hardened paste is governed by the water-cement ratio and the extent to which the chemical reaction between the cement and water has progressed.

Concrete must be durable enough to withstand extreme exposure conditions and maintain long life with a minimum of upkeep. Concrete is used widely outdoors and is exposed to the destructive action of weathering. The prime essential of a durable concrete is watertightness. If water cannot penetrate the concrete to any appreciable extent, repeated freeze-thaw cycles will cause little or no deterioration of the concrete.

For concrete, the most destructive factor in weather is freezing and thawing of concrete while it is wet or moist. Destruction of the concrete may be caused by expansion of the paste, of some of the particles of the aggregate, or by a combination of both. The introduction of entrained air into the concrete can help prevent this destruction.

Concrete must be strong enough to carry the heavy loads placed on it. Strength in concrete usually refers to compressive strength. Strength often receives greater attention that either durability or watertightness. Yet strength is the quality most easily controlled during construction and is the one most easily checked by tests of samples taken on the job. Fortunately, the same precautions which increase the strength of concrete also improve its durability and watertightness to about the same degree. However, it is possible for concrete to be strong

21032

enough for its intended purpose and yet not be sufficiently durable and watertight for the conditions to which it is subjected.

If concrete is to be exposed to weather or other severe exposure conditions, it should be watertight. This requires a watertight paste. Tests show that a watertight paste depends on the water-cement ratio and the extent to which the concrete has been cured or kept moist prior to exposure.

For certain uses, concrete should be able to resist the abrasive action of wheeled vehicles, foot traffic, flowing water, etc. The same factors that increase durability, strength, and watertightness also increase the ability of concrete to resist abrasion or wear. When wear resistance is of primary importance, aggregate particles should be hard and tough. They should be as hard as the cementing paste.

THE PROPERTIES OF CONCRETE

Concrete hardens in the presence of water. Most materials deteriorate when they become wet, but concrete actually gains strength in the presence of water. This characteristic is of great importance in the construction of structures, especially foundations and footings in wet locations.

Since concrete is composed of mineral materials, it does not corrode or decay. It also resists vermin, termites, and rodents.

Freshly mixed concrete can be formed into practically any shape. Many materials can be molded only when heated and require elaborate casting facilities. Concrete, however, can be molded at normal temperatures, which gives it tremendous flexibility.

Concrete will withstand heat and fire because it is made of materials that will not burn. Portland cement is manufactured at temperatures from 2,600 to 3,000 deg. F. Aggregates are also incombustible. Thus, concrete has a high fire resistance which is desirable in any construction, especially in areas where fire protection is inadequate.

Concrete is widely available. Portland cement and aggregates are available in all parts of the country at reasonable prices.

VARIABLES THAT INFLUENCE CONCRETE QUALITY

All the desirable properties of hardened concrete are controlled by the amount of water in proportion to the amount of cement used in the mix. This relationship is known as the water-cement ratio and is expressed in terms of gallons of water per bag of cement.

There are several reasons for specifying grading limits and maximum

21033

aggregate size. The grading and maximum size of aggregates affect relative proportions, workability, economy, porosity, and shrinkage of concrete.

Variations in grading may seriously affect uniformity of concrete from one batch to another. Very fine sands are uneconomical and very coarse sands produce harsh, unworkable mixes. In general, aggregates that do not have a large deficiency or excess of any size produce the most satisfactory results.

The entrainment of air in concrete significantly improves the resistance of concrete to the adverse effects of freezing and thawing, as well as to the damaging effects of various de-icing chemicals. This improvement is particularly desirable in situations where the concrete will be saturated with water.

As water freezes it expands (up to 9 per cent), causing pressures that can rupture concrete and cause scaling. Air-entrained concrete has microscopic bubbles that provide reservoirs which relieve the pressure as excess water is forced into them, thus preventing damage to the concrete. The bubbles or air voids continue to serve their purpose during repeated cycles of freezing and thawing, improving resistance many times over that of concrete containing no entrained air.

Air entrainment has advantages in both plastic and hardened concrete:

1. Plastic Concrete

   a. Air entrainment lowers the water and sand requirement per cubic yard.
   b. Air-entrained concrete can be worked more easily.
   c. Air entrainment tends to reduce aggregate segregation and bleeding.
   d. Air-entrained concrete may be finished earlier than non-air-entrained concrete. Caution: Do not mistake the absence of bleeding water for the setting of concrete and attempt to finish it too soon.

2. Hardened Concrete

   a. Air entrainment greatly improves concrete's resistance to freeze-thaw action.
   b. Air entrainment is effective in preventing serious surface scaling caused by de-icing chemicals.
   c. Air-entrained concrete is more watertight than concrete with no entrained air.

21034

TEST OR DISCUSSION POINTS

1. What is concrete?
2. What are the "inert" materials?
3. What is the composition of the paste?
4. What properties are desired in fresh concrete?
5. Name four properties desired in hardened concrete.
6. Explain how the following variables influence the properties of concrete.
   a. Water-cement ratio
   b. Aggregate grading and maximum size
   c. Air entrainment

21035

Area V

SAFETY INSTRUCTION

Safety in the food industry cannot be overemphasized. It is essential that the instructor stress safety, not as a process but as part of a process. Safety is part of cooking; safety is part of care and maintenance; safety is part of any preparation process.

Safety instruction should be related to the various production and serving processes. The instructor should point out the hazards commonly associated with food production work and should stress common causes of accidents. The student should be made to understand that the right way is always the safe way.

The student must understand that the end purpose of safety instruction is to prevent accidents by eliminating causes of accidents. The instructor should emphasize the importance of first aid. A small scratch can become costly if proper first aid is not given immediately.

Materials from the National Safety Council, local health departments, American Red Cross, and Civil Defense Agency will be valuable in presenting this subject area.

Accident Prevention; First Aid

Essential learning (Skill and knowledge)	Scope of instruction (Suggested content)	Information (Technical and related)
To know the importance of safety rules	Basic principles of safety as related to all phases of food preparation	Orientation of new employees
Accident causes	Correct attitude towards accidents	
	Unsafe acts:	Proper supervision

CONCRETE INFORMATION
PORTLAND CEMENT ASSOCIATION
pca

NOTE: *Measurements are expressed in U.S. units. Water-cement ratio is expressed as U.S. gallons per 94-lb. bag of cement, followed by a weight ratio, pounds of water per pound of cement.*

Fundamental Facts About Concrete

CONCRETE CAN BE CONSIDERED to be made of two components, aggregates and paste. Aggregates are generally classified into two groups, fine and coarse. Fine aggregates consist of natural or manufactured sand with particle sizes smaller than about ¼ in.; coarse aggregates are those with particle sizes greater than about ¼ in. The paste is composed of cement, water, and sometimes entrained air.

Cement paste ordinarily constitutes 25 to 40 per cent of the total volume of concrete. As shown in Fig. 1, the absolute volume of cement is usually between 7 and 15 per cent (4 to 8 bags per cubic yard) and the water from 14 to 21 per cent (28 to 42 gal. per cubic yard). Air contents in air-entrained concrete range up to about 8 per cent of the volume of the concrete.

Since aggregate makes up about 60 to 80 per cent of the concrete, its selection is important. Aggregate should consist of particles having adequate strength and resistance to exposure conditions, and should not contain materials having injurious effects. A smooth gradation of particle sizes is desired for efficient use of the cement and water paste. In the following discussion, it is assumed that suitable aggregate is used.

Fig. 1. Range in proportions of materials used in concrete. Bars 1 and 3 represent rich mixes with small aggregates. Bars 2 and 4 represent lean mixes with large aggregates.

Fig. 2. Cross-section of concrete. Cement and water paste completely coats each aggregate particle and fills all of the space between particles.

In properly made concrete, each particle of aggregate is completely coated with paste. Also, all of the space between aggregate particles is completely filled with paste. This is illustrated in Fig. 2, which shows a section cut through hardened concrete. It can be shown that the quality of the concrete is greatly dependent upon the quality of the paste.

Quality of paste is dependent upon the ratio of water to cement used, and the extent of curing. The cementing properties of the paste are due to the chemical reactions between cement and water. These reactions, called hy-

© Portland Cement Association 1966

Fig. 3. The durability of concrete exposed to freezing and thawing is affected by the quality of the paste. Air-entrained concrete with a low water-cement ratio is highly resistant to repeated freeze-thaw cycles.

dration, require time and favorable conditions of temperature and moisture. They take place very rapidly at first and then more and more slowly for a long time under favorable conditions.

More water is used in mixing concrete than is required for complete hydration in order to make the concrete plastic and workable. However, as the paste is thinned with water, its quality is lowered; it has less strength and is less resistant to weather. For successful results, a proper proportion of water to cement is essential.

Resistance to Freezing and Thawing

Concrete is used in structures and pavements that are expected to have long life and low upkeep. One requirement of such concrete is high resistance to anticipated exposure conditions. The most destructive factor of weather is freezing and thawing while the concrete is wet or moist. Deterioration may be caused by expansion of the water in the paste, by expansion of some of the aggregate particles, or by a combination of both. Air entrainment improves resistance to this deterioration.

Destructive expansion of water in the paste during freezing is accommodated in air-entrained concrete. Air bubbles in the paste provide chambers in which the expansive force is relieved.

When freezing occurs in concrete exposed to wet conditions for a sufficiently long time to saturate some aggregate particles, destructive hydraulic pressures may be generated. Water displaced from these aggregate particles during the formation of ice is unable to escape fast enough through the surrounding paste to prevent such pressure.

Fig. 4. Relationship between freeze-thaw resistance and water-cement ratio for air-entrained and non-air-entrained concretes. High resistance to freezing and thawing is associated with entrained air and low water-cement ratio.

21037

However, under nearly all exposure conditions, a paste of good quality, protected with entrained air, is able to prevent aggregate particles from becoming saturated. This enables air-entrained concrete to withstand freezing and thawing.

The mechanics of frost action in concrete is considerably more complicated than indicated by the above explanation. More comprehensive and accurate explanations of this subject are available.

Fig. 4 illustrates that within the range of water-cement ratios normally used, air-entrained concrete is much more resistant to freeze-thaw cycles than non-air-entrained concrete. Also, concrete with a low water-cement ratio is more durable than concrete with a high water-cement ratio. "Durability," as shown in Fig. 4, is a relative measure of the number of cycles of freezing and thawing required to produce a certain amount of deterioration in test specimens. Air-entrained concrete with a low water-cement ratio will withstand a great number of cycles of freezing and thawing without showing distress.

Watertight Concrete

Where concrete is exposed to weather or other severe exposure conditions, it is important that it be watertight. Such concrete requires a watertight paste. Tests show that watertightness of paste depends on the water-cement ratio and the extent to which the chemical reactions between the cement and water have progressed. Test results

Fig. 5. Test apparatus for measuring watertightness of hardened concrete. Specimens are locked into the metal containers. Graduates below collect water that leaks through.

Fig. 6. Effect of water-cement ratio and curing on watertightness. Note that leakage is reduced as the water-cement ratio is decreased and the curing period increased.

obtained by subjecting non-air-entrained mortar discs to 20 psi water pressure are shown in Fig. 6.

In these tests, the mortar discs that were moist-cured for 7 days had no leakage when made with 5.6 gal. of water per bag of cement (0.50). Leakage was greater in mortars made with higher water-cement ratios. Also, for each water-cement ratio, the leakage became less as the length of curing period was increased. In the discs with 9 gal. per bag (0.80), the mortar still permitted leakage after being cured a month.

Air entrainment improves watertightness by increasing density through improved workability and reduced segregation and bleeding. Because the total water requirement of air-entrained concrete is less, the paste will have a lower water-cement ratio and will therefore be more watertight.

Watertight concrete must be free from cracks and honeycomb.

Strength of Concrete

The compressive strength of concrete is important in design of structures. In pavements and other slabs on ground, the flexural strength of the concrete is often used for design purposes. The principal factors affecting strength are the water-cement ratio and the extent to which hydration has progressed. Fig. 8 shows the compressive strengths for a range of water-cement ratios at different ages. Tests were made on 6-in.-diameter specimens that were 12 in. in height. Note that strengths increase as the water-cement ratios decrease, and that strengths increase with age. Flexural, tensile, and bond strengths are similarly influenced by water-cement ratio.

Fig. 8 also gives the typical age-strength relationships for air-entrained and non-air-entrained concretes. When

21038

Fig. 7. Testing a 6x12-in. concrete cylinder in compression. The load on the test cylinder is registered on the scale.

more precise relationships are required, curves should be developed for the specific materials and cement contents that will be used. In general, greater strengths may be secured with lower water-cement ratios.

Air-entrained concrete requires less water for the same workability as non-air-entrained concrete. Hence, the water-cement ratio will be decreased when a given cement factor is maintained. Therefore, the lower water-cement ratio required for air-entrained concrete does not necessarily imply an increased cement factor.

Resistance to Abrasion

Concrete floors, pavements, and dam spillways are subjected to abrasion; hence resistance to abrasion or wear is important in these applications of concrete. Test results indicate that abrasion resistance is dependent principally upon the strength of the concrete. Strong concrete is more resistant to abrasion than weak concrete.

Fig. 10 shows results of abrasion tests on concretes of different compressive strengths. The tests were conducted by rolling steel balls under pressure over the surface of concrete specimens. Each specimen was subjected to the same number of revolutions. Since compressive strength is dependent upon water-cement ratio and curing, it is evident that a low water-cement ratio and adequate curing are necessary for abrasion resistance.

Moist Curing

The increase in strength with age continues as long as drying of the concrete is prevented. When the concrete

Fig. 8. Typical age-strength relationships based on compression tests of 6x12-in. cylinders (left, *for air-entrained concrete;* right, *for non-air-entrained concrete).*

21039

Fig. 9. Test apparatus for measuring abrasion resistance of concrete. Steel balls under pressure are rolled over the surface of the specimen.

is permitted to dry, the chemical reactions slow down or stop. It is, therefore, desirable to keep concrete continually moist as long as possible. This is illustrated in Fig. 11.

When moist curing is interrupted, the strength increases for a short period and stops. However, if moist curing is resumed, the strength will again increase. Although this can be done in a laboratory, it is difficult on most jobs to resaturate concrete. It is best to moist-cure the concrete continuously from the time it is placed until it has attained the desired quality.

The effects of concrete temperature during mixing and curing are discussed in *Hot-Weather Concreting** and *Cold-Weather Concreting.**

Fig. 10. Effect of compressive strength on the abrasion resistance to concrete. High-strength concrete is highly resistant to abrasion.

Volume Stability of Concrete

Hardened concrete undergoes small changes in volume due to changes in temperature and moisture content, and due to sustained stress. These volume changes may range from about 0.01 to 0.08 per cent in terms of length. Thermal volume changes are about the same as those for steel.

Concrete kept continually moist will remain almost constant in volume; actually a slight expansion may occur. When permitted to dry, concrete will shrink. The amount of shrinkage is dependent upon several factors, such as amounts of mixing water and aggregate used, properties of the aggregate, size of the specimen, relative humidity and temperature of the environment, and method of curing. Concrete subjected to stress will deform elastically. Sustained stress will result in a deformation called creep. The rate of creep deformation decreases with time.

The magnitude of volume changes and factors influencing them are discussed in *Volume Changes of Concrete.**

Fig. 11. Strength of concrete continues to increase as long as moisture is present for hydration of cement.

*Available free in the United States and Canada from the Portland Cement Association.

21840

Properties of Fresh Concrete

The foregoing discussion has dealt with properties of hardened concrete. Although freshly mixed concrete remains plastic only a short time, its properties are important, however, because they affect the quality and cost of hardened concrete.

With a given amount of water and cement paste, an increase in the amount of aggregate causes stiff mixes. Consequently, stiff mixes are more economical in use of materials. On the other hand, stiff mixes may require more labor in placing; the additional cost may offset savings in materials. In general, thin members and heavily reinforced members require more plastic mixtures than large members containing little reinforcement.

Concrete of *plastic* consistency does not crumble, but flows sluggishly without segregation. Mixtures of such consistency are suitable for most concrete work.

The ease or difficulty of placing and consolidating concrete is called workability. An experienced workman can readily judge when fresh concrete has adequate workability for use in a given situation. Concrete should be workable but should not segregate nor should it bleed excessively. Bleeding is the movement of water to the surface of freshly cast concrete. Since excessive bleeding may increase the water-cement ratio at the surface, a weak layer having poor durability may result, particularly if finishing operations take place while this excess water is present.

Generally the most economical mix is one that has the highest proportion of aggregate to cement and yet is workable at the water-cement ratio required for strength, durability, and other properties.

21041

SAMPLING AND TESTING PLASTIC CONCRETE

A complete discussion covering all methods for sampling and testing both plastic and hardened concrete would be too lengthy for inclusion in this unit. However, a general knowledge of sampling and testing plastic or fresh concrete will greatly benefit all concrete workers.

The need for standardization in testing led to the formation of the American Society for Testing and Materials (ASTM). All tests should be made in accordance with the standard methods of the ASTM.

SAMPLING FRESH CONCRETE

ASTM C172, "Standard Method of Sampling Fresh Concrete," covers the procedure for obtaining samples of fresh concrete from stationary and paving mixers, and from truck mixers, agitators, or dump trucks.

The sample must consist of not less than 1 cu.ft. when it is to be used for strength tests. Smaller samples may be permitted for routine air content and slump tests.

Sampling procedures shall include the use of every precaution that will assist in obtaining samples that will be representative of the true nature and condition of the concrete sampled, as follows:

(a) Stationary mixers, except paving mixers: Pass a receptacle through the discharge stream at about the middle of the batch.

(b) Paving mixers: After mixer has discharged onto subgrade, collect portions from at least five different points to be representative.

(c) Revolving drum truck mixers or agitators: Take three or more portions in regular increments throughout discharge of entire batch. Sampling is done by repeatedly passing a receptacle through the entire discharge stream or by diverting the stream completely so that it discharges into a container such as a wheelbarrow.

(d) Open-top truck mixers, agitators, dump trucks, or other types of open-top containers: Samples must be taken by whichever of the procedures described in Paragaphs (a), (b), or (c) is most applicable.

The sample must be transported to the place where test specimens are to be molded or where the test is to be made, and then remixed with a shovel the minimum amount to ensure uniformity. The sample must be protected from sun-

light and wind during the period between taking and using, which shall not exceed 15 minutes.

TESTS FOR CONSISTENCY

ASTM Designation C143, "Standard Method of Slump Test for Consistency of Portland Cement Concrete," is a test method covering the procedure for determining slump of concrete both in the laboratory and in the field.

The slump test may be used as a rough measure of the consistency of concrete--how wet or dry it is. This test is not to be considered as a measure of workability or proper water content, nor should it be used to compare mixes of entirely different proportions or containing different kinds of aggregates. Any change in slump on the job indicates changes have been made in grading or proportions of the aggregates or in the water content. The mix should be corrected immediately to get the proper consistency by adjusting amounts and proportion of sand and coarse aggregate. Care should be taken not to change the total amount of water specified for mixing with each bag of cement.

In making the slump test, the test specimen is made in a mold or "slump cone" of 16-gage galvanized metal in the form shown in Fig. 20. The diameter is 8 in. at the base and 4 in. at the top, and the height is 12 in. The base and top are open. The mold is provided with foot pieces and handles as shown.

Fig. 20. Mold for slump test.

21043

The concrete sample for a slump test should be taken immediately prior to placing the concrete in the forms. The mold is dampened and placed on a flat surface such as a smooth plank or slab of concrete. The mold is filled with concrete to about one-third its volume. Then the concrete is rodded with 25 strokes of a 5/8 in. steel rod about 24 in. long, bullet pointed at the lower end (Fig. 21). The filling is completed in two more layers. Each layer is rodded 25 times and each rod stroke penetrates into the underlying layer. After the top layer has been rodded, it should be struck off by means of a screeding and rolling motion of the tamping rod. The mold is removed by gently raising it vertically immediately after being filled. The mold is then gently placed beside the concrete specimen and the slump is measured as shown in Fig. 22. For example, if the center of the top of the slumped pile of concrete is 5 in. below the top of the cone, the slump of the concrete is 5 in.

Fig. 21. The slump test shows consistency of concrete. Here, rodding concrete in cones ensures complete filling of the mold.

Fig. 22. Slump is measured from rod laid across the top of the slump cone. This amount of slump indicates a medium-wet concrete mixture.

BALL PENETRATION TEST

A convenient supplementary test for the consistency of concrete, but not a substitute for the slump test, is provided by ASTM Method C360, "Tentative Method of Test for Ball Penetration in Fresh Portland Cement Concrete." This test is sometimes referred to as the "Kelly Ball" test. It involves determining the depth to which a 6-in.-diameter metal hemisphere, weighted to 30 ± 0.1 lb., will sink into the fresh concrete. It has the advantage over the slump test of not involving the molding of a specimen and permitting the testing of concrete in a wheelbarrow or other container, or even in the forms. The test can be made quickly and thus provides a convenient means for the routine checking of consistency for control purposes. The results cannot be translated quantitatively into terms of slump and should not be used as a basis for acceptance or rejection of the concrete.

To avoid the effects of boundary conditions, the ball penetration test must be made on a reasonably large sample. The ASTM Method requires a depth of concrete of at least 8 in. and a minimum lateral dimension of about 18 in. Disturbance or vibration of the sample during test must be avoided and care must be taken that the weight is allowed to settle freely but without impact. The reported result should be an average of at least three readings.

UNIT WEIGHT TEST

The standard test for unit weight of fresh concrete (ASTM C138) is similar to that used for unit weight of aggregates (ASTM C29). The same measuring containers are used, except that for the test on concrete the 1/2-cu.ft. measure is used when the nominal maximum size of aggregate does not exceed 2 in., and the 1-cu.ft. measure when the maximum size of aggregate is greater than 2 in. The concrete is placed in three approximately equal layers. Each layer is rodded and the side of the measure is then tapped with the rod 10 to 15 times or until no large bubbles of air appear on the layer. The measure is struck off level full with a flat cover plate. Excess concrete is cleaned off and the net weight of the concrete is determined.

TESTING FOR AIR CONTENT

There are various methods for determining the air content of fresh concrete. Three methods have been standardized by the ASTM:

The Pressure Method (ASTM C231) is practical for field testing of all concretes except those made with highly porous and lightweight aggregates.

The Volumetric Method (ASTM C173) is practical for field testing of all concretes, but is particularly useful for concrete made with lightweight and porous aggregates.

The Gravimetric Method (ASTM C138) requires accurate knowledge of

21045

Appendix A

OCCUPATIONS IN THE FOOD SERVICE INDUSTRY

Instructors and student advisors should be familiar with the kinds of entry jobs available in the food service industry. The information included in this appendix covers a wide variety of jobs.[1] It should be equally valuable in counseling applicants for the training program and students already enrolled.

The job summary descriptions given in this appendix are not all-inclusive. They are not offered as complete job descriptions but as thumbnail descriptions of a few positions in the industry. It should be noted that job titles may vary from one food service establishment to another. It is not uncommon for one establishment to use the term dinner or first cook, while another restaurant will use the title of second cook for the same job.

In many hotels and restaurants two or more of the jobs listed or described may be combined; for example, the second cook may do all of the work normally assigned to the soup, sauce, roast, and broiler cooks. Job titles are used interchangeably in many instances. Regardless of terminology used, students and instructors should be familiar with the various occupational possibilities. (See *Occupational Outlook Handbook, 1966–67 edition,* U.S. Government Printing Office, Washington, D.C.)

In addition to knowing the types of jobs available, instructors and counselors should be familiar with laws and local regulations governing employment of minors and women. In areas requiring work permits for part-time student employment, it is essential that counselors and instructors know the procedure for acquiring them. Some sections of the Civil Rights Act of 1964 have a real bearing on the employment of women.[2] In some instances hours of employment for women are regulated by the State or local communities.

[1] See Teaching Materials Nos. 8 and 12.

[2] Public Law 352, 88th Congress, H.R. 7152, July 2, 1964.

The quantity food training program should prepare students for entry jobs in the food service industry. Training should be sufficiently thorough to enable graduates to advance, after a period of experience, to any or all positions described below. Jobs listed first are entry jobs; those with summary descriptions are jobs to which graduates may advance after varying periods of experience.

Kitchen helper	Storeroom clerk
Cook's helper	Receiving clerk
Salad preparer	Food checker
Pantry helper	Host or hostess
Dish machine operator	Counterman
Baker's helper	Cake decorator

Fry cook (short order cook, breakfast cook): Fries meats, fish, fowl, and vegetables; is responsible for making sandwiches and preparing wheat cakes and other breakfast dishes. He may assist the second cook. The term short order cook is used where the fry cook is responsible for cooked-to-order foods in counter-type operations.

Vegetable cook: Directs the preparation, cleaning, and cooking of vegetables. He is responsible to the chef. In many establishments the work done by the vegetable cook is combined with that of the second cook.

Roast cook: Roasts, bakes, and carves meats, fish, and fowl; may prepare gravies and stuffings. Work may be combined with that of the second cook or dinner cook.

Garde manger: Supervises the cold meat and sandwich department; makes salad dressings, cocktail sauces; makes seafood, fish, and shrimp salads and cocktails; makes and decorates canapés, hors d'oeuvers, and appetizers. The work of the garde manger is often done by pantry men or women. This position is usually found in very large establishments.

Meat cutter (butcher): Cuts, trims, and prepares meats for roasting, frying, broiling, and

specific gravities and absolute volumes of concrete ingredients. It is impractical as a field test method but can be used satisfactorily in the laboratory.

A field test for checking possible changes in air content or mix proportions is the unit weight test. The only equipment needed to perform this test is a sturdy container of known volume, preferably 1/4 or 1/2 cu.ft., and an accurate balance. Changes in air content generally result in changes in the unit weight of concrete from one batch to another.

One way to check the approximate air content of fresh concrete is with a pocket-size air indicator, shown in Fig. 23. The small container is filled with a representative sample of mortar from the fresh concrete. The tube is then filled with alcohol and, with the thumb over the open end, the tube is shaken to remove the air from the mortar. By using a calibration chart, the approximate air content is determined from the drop in the level of the alcohol. Since this test can be performed in only a few minutes, it is especially useful for estimating the air content of fresh concrete. However, it is not a substitute for the more accurate pressure and volumetric methods.

Fig. 23. Air indicator.

FOLLOW-UP TESTS

Follow-up tests to determine the effectiveness of the field control methods are made on many jobs. These tests are usually for compressive strength or flexural strength. The specimens should be made and cured in accordance with "Standard Method of Making and Curing Concrete Compression and Flexure Test Specimens in the Field" (ASTM C31). For laboratory work, "Standard Method of Making and Curing Concrete Compression and Flexure Test Specimens in the Laboratory" (ASTM C192) may be used. The testing of the specimens should be done in accordance with "Standard Method of Test for Compressive Strength of Molded Concrete Cylinders" (ASTM C39) and "Standard Method of Test for Flexural Strength of Concrete (Using Simple Beam and Third-Point Loading)" (ASTM C78).

At times it is desirable to make compressive or flexural strength tests of specimens taken from the hardened concrete. The work should be done as specified in "Standard Methods of Securing, Preparing and Testing Specimens from Hardened Concrete for Compressive and Flexural Strengths" (ASTM C42).

21046

STRENGTH TEST CYLINDERS (ASTM C31)

Test specimens are sampled from concrete being used in construction to determine if the concrete has the specified compressive strength. Field control specimens of various ages indicate the rate of strength gain and the effectiveness of job-site curing. Meticulous care must be exercised in the molding, protection, and curing of strength test cylinders.

In making the compressive strength field test, a sample of the concrete is taken at three or more regular intervals throughout the discharge of the entire batch. However, samples are not to be taken at the beginning or end of discharge. Before filling the molds, the individual portions of the sample should be remixed with a shovel to ensure uniformity. No water should be added. The batch of concrete thus sampled is noted as to its location in the work, the air temperature, and any unusual conditions.

The compressive test specimen is made in a watertight cylindrical mold. Standard cylindrical molds are 6 in. in diameter by 12 in. in length if the coarse aggregate does not exceed 2 in. in nominal size. The mold is filled in three equal layers. Each layer is rodded with 25 strokes of a 5/8 in. round steel rod about 24 in. long, with bullet-pointed tip. When rodding the second and third layers, the rod should penetrate through into the concrete layer underneath. Reinforcing rods or other tools should not be used as the tamping rod. After the top layer has been rodded, the surface of the concrete is struck off with a trowel and immediately covered with a glass or metal plate to prevent evaporation. The side of the mold should not be tapped or otherwise vibrated when it is being filled.

Molds should be placed on a rigid horizontal surface that will be free from vibration and other disturbances. During the first 24 hours, test specimens should not be moved. They should be stored under conditions that will prevent the loss of moisture and also maintain the temperature within a 60 to 80 deg. F. range. Send the cylinders to a laboratory as soon as possible for standard curing.

Standard procedures provide for curing the specimens either in the laboratory or in the field. Laboratory curing gives a more accurate indication of the potential quality of the concrete. Field-cured specimens may give a more accurate interpretation of the actual strength in the structure or slab, but they offer no explanation of whether any lack of strength is due to error in proportioning, poor materials, or unfavorable curing conditions. On some jobs both methods are used, especially when the weather is unfavorable to proper interpretation of the tests. The laboratory test result is the one that always prevails.

Concrete specimens at all ages should be protected from rough handling. In all cases, the specimens should be kept upright until they have hardened. If these precautions are disregarded, the concrete test specimens will indicate lower than normal strengths. Rough handling and lack of proper curing usually result in erratic and low-strength tests.

21047

At the laboratory, compression tests are made in accordance with ASTM Designation C39, "Standard Method of Test for Compressive Strength of Molded Concrete Cylinders."

The specimen is placed in a testing machine where a load is applied and increased until the specimen fails. After this, the compressive strength of the specimen is calculated to the nearest 10 psi.

APPLICATION

Discuss slump test, consistency, and concrete test cylinders. Show mold and demonstrate proper procedures for slump test. Show mold for compressive test and discuss proper methods of obtaining specimens.

TEST OR DISCUSSION POINTS

1. What is the ASTM and why was it formed?
2. Explain why a slump test is used.
3. What would a change in slump indicate?
4. When should a concrete sample be taken for a slump test?
5. Explain the complete procedure for making a slump test.
6. After the cone is removed from a concrete specimen, how is the slump measured?
7. Of what value are compressive tests?
8. Explain the procedure for obtaining test cylinders.
9. How should preliminary storage and curing of compressive test specimens be handled?
10. What precautions should be observed when handling and shipping compressive test specimens?
11. Name some factors affecting air content in concrete.
12. Explain how you would make a simple field test for checking possible changes in air content of fresh concrete.

TOOLS AND MATERIALS

Slump cone, rod, and rule
Compressive test mold

21049

PORTLAND CEMENT: HISTORY, MANUFACTURE, CHARACTERISTICS, AND TYPES

Portland cement, often called the "magic powder," is a finely ground material consisting primarily of compounds of lime, silica, alumina, and iron. When mixed with water, it forms a paste which hardens and binds the aggregates (sand, gravel, crushed rock, etc.) together to form a hard durable mass called concrete. Thus, cement is one ingredient of concrete.

SETTING AND HARDENING

When portland cement is mixed with water, a paste is formed which first sets--that is, becomes firm--and then hardens. The setting and hardening are due to a chemical reaction called hydration between the cement and water. This chemical reaction builds up a strong internal structure which makes concrete hard, strong, durable, and watertight. The set and subsequent hardening process are the same whether the cement is used alone or in combination with aggregates. If the concrete is kept moist, the reaction will continue for years and the concrete will become progressively stronger and more durable.

HISTORY OF CEMENTING MATERIALS

The history of cementing materials goes back to the time when ancient man first abandoned the cave and thought about building a home. His first problem was finding a material to chink the stones and to keep out the cold. The Assyrians and Babylonians used clay for this purpose. Then the Egyptians discovered lime and gypsum mortar which they used in their pyramids. The Greeks made further improvements, and finally the Romans perfected a cement that produced structures of remarkable durability. The Colosseum and the great system of aqueducts and other cement-bonded structures built by the Romans are in an excellent state of preservation today.

Despite the early use of these materials, little was known of their chemistry and no substantial advance was made in the manufacture of cementing materials from the time of the Romans until 1756. In that year, John Smeaton, who had been employed by the English government to build a lighthouse in the English Channel, discovered that a mixture of limestone and clay, when burned, would harden into a solid mass under water as well as in air. Smeaton's discovery led the way to rapid improvement of cement and masonry construction.

-91-21050

In 1824, Joseph Aspdin took out a patent in England for the manufacture of an improved cement produced by heating a mixture of limestone and clay and crushing the resulting product to a fine powder. He called this powder "portland" cement, because it produced a yellowish-gray concrete which resembled stone quarried on the Isle of Portland, England. Aspdin is generally recognized as the father of the modern portland cement industry.

In 1872, the first cement plant was built in North America at Coplay, Pa., to give birth to the portland cement industry in North America.

RAW MATERIALS

Raw materials for cement may be divided into those supplying the lime component (calcareous), the silica component (siliceous), the alumina component (argillaceous), and the iron component (ferriferous). Portland cement consists of a combination of the following compounds:

1. Lime
2. Silica
3. Iron oxide
4. Alumina
5. Gypsum (added after burning)

Fig. 8. Raw materials for portland cement.

21051

The term "limestone" is used to include all carbonate rocks containing major quantities of calcium. Limestones are composed essentially of calcium carbonate, varying minor percentages of magnesium carbonate, and mechanically admixed impurities of clay and sand. Clay and sand are not objectionable impurities when the rock is used for the manufacture of portland cement.

Cement rock is a low-magnesium limestone containing clay.

Marls are earthy, friable accumulations of calcareous materials secreted by plants and animals in lakes and marshes. Over long periods of time the skeletal remains of plants mixed with shells of animals may form beds as much as 30 ft. thick, containing substantial tonnages of material suitable for cement manufacture.

Shell marls consist of mixtures of fossil shells, shell fragments, and varying amounts of clay and sand.

Oyster and clam shells of recent origin have been collected and burned for lime from Nova Scotia to Texas. Tonnage adequate for cement manufacture, however, is not known on the Atlantic coast of North America. In San Francisco Bay, shells occur in brackish water deposits as much as 30 ft. thick and are suitable for cement manufacture. Along the Gulf of Mexico, oyster shells are the principal source of lime for cement manufacturers.

Coquina shells, used in Florida, are excavated under water and cleaned completely or partially of their sand by washing.

Clay and shale must be added where alumina and silica are not present in the limestone in sufficient amounts.

MANUFACTURING PROCESS

Portland cement is manufactured from carefully selected materials and by closely controlled processes. The process starts by blending in proper proportions limestone, marl, or other calcareous materials with clay, shale, or blast-furnace slag. This mixture is heated in a rotary kiln to a temperature of approximately 2,600 to 3,000 deg. F., when it forms a clinker. The clinker is cooled and then pulverized. A small amount of gypsum is added to regulate the setting time. The pulverized product is finished portland cement. It is ground so fine that nearly all of it will pass through a 200-mesh sieve (40,000 openings to the square inch). The finished product is then stored in silos from which it is bagged or loaded for shipment.

PACKING AND STORAGE OF PORTLAND CEMENT

Much of the cement now being used is shipped in bulk by rail or truck to ready mixed concrete producers and block manufacturers, or direct to the construction site. It is quickly unloaded by automatic equipment into silos or hoppers

21052

for storage. Cement is also sold in paper bags. Each bag holds 1 cu.ft. of cement and weighs 94 lb. Cement is often measured in barrels equal to 4 bags or 376 lb. The weight of a bag of masonry cement (70 lb. average) is printed on the bag.

Portland cement will retain its cementing quality indefinitely if it does not come in contact with moisture. Thus, it should be stored in a location as dry and airtight as possible.

When bagged cement is in storage for long periods it sometimes acquires a "warehouse pack." This can usually be corrected by rolling the bag on the floor. When used it should be free flowing and free of lumps. If cement contains lumps that cannot be easily broken up, it is advisable not to use it.

CLASSIFICATION OR TYPES OF PORTLAND CEMENT

Portland cement is a type of cement, not a brand name. Each manufacturer of cement makes portland cement. Note that the words "portland cement" are not capitalized. All portland cements are hydraulic cements. This means they will set and harden under water. Portland cements are made to meet the American Society for Testing and Materials' standard specifications ASTM Designation:

C150 Portland Cement, Types I through V
C175 Air-Entraining Portland Cement
C205 Portland Blast-Furnace Slag Cement
C340 Portland-Pozzolan Cement

The first of these specifications, ASTM Designation C150, covers five types of portland cement:

Type I, normal portland cement, is a general-purpose cement suitable for all uses when the special properties of the other types are not required. It is used in pavement and sidewalk construction, reinforced concrete buildings and bridges, railway structures, tanks and reservoirs, culverts, water pipe, masonry units, and for all uses of cement or concrete not subject to sulfate attack from soil or water or where the heat generated by the hydration of the cement will not cause an objectionable rise in temperature.

Type II, modified portland cement, has a lower heat of hydration than Type I and generates heat at a slower rate. It also has improved resistance to sulfate attack. It may be used in structures of considerable size such as large piers, heavy abutments, and heavy retaining walls, to minimize temperature rise, especially when the concrete is placed in warm weather. In cold weather, when the heat generated is an advantage, Type I or III cement may be preferable. Type II cement is also intended for places where added precaution against moderate sulfate attack is important, as in drainage structures where sulfate concentrations in ground waters are higher than normal but are not unusually severe.

Type III, high-early-strength portland cement, is used when high strengths are desired at very early periods--from one to three days. It is used when it is desired to remove forms as soon as possible or to put the concrete into service quickly, or in cold weather construction to reduce the period of protection against low temperatures. It is also used when the high strengths desired at early periods can be secured more satisfactorily or more economically than by using richer mixes of Type I cement.

Type IV, low-heat portland cement, is a special cement for use where the amount and rate of heat generated must be kept to a minimum. The development of strength is also at a slower rate. It is intended for use in mass concrete such as large gravity dams where temperature rise resulting from the heat generated during hardening is a critical factor.

Type V, sulfate-resistant portland cement, is a special cement intended for use only in construction exposed to severe sulfate action, such as in some western states having soils or waters of high alkali content. It has a slower rate of strength gain than normal portland cement.

Air-entraining portland cements are covered by ASTM C175 and are designated as Types IA, IIA, and IIIA. These correspond to Types I, II, and III, respectively, in ASTM C150. In these cements, small quantities of air-entraining materials are incorporated by intergrinding them with the clinker during manufacture. These cements have been developed to produce concrete that will resist severe frost action as well as the effects of chemicals applied for snow and ice removal. Concrete made with these cements contains tiny, well-distributed, completely separated air bubbles. The bubbles are so minute that there are billions of them in a cubic foot of air-entrained concrete.

White portland cement is manufactured from raw materials that produce pure white color. It is used primarily for architectural purposes such as precast curtain wall and facing panels, terrazzo surfaces, stucco, cement paint, tile grout, and decorative concrete. Its use is recommended wherever white or colored concrete or mortar is desired. The only difference between white and gray cement is its color.

Portland blast-furnace slag cement (ASTM C205) includes two types of cement--Type IS, portland blast-furnace slag cement, and Type IS-A, air-entraining portland blast-furnace slag cement. In these cements, granulated blast-furnace slag of selected quality is interground with portland cement clinker. These cements can be used for the same type of concrete work as Type I or Type IA portland cement.

Portland-pozzolan cement (ASTM C340) also is available in two types--Type IP, portland-pozzolan cement, and Type IP-A, air-entraining portland-pozzolan cement. In these cements, pozzolan (such as volcanic ash or volcanic

rock) is blended with ground portland cement clinker. This cement is used largely for underwater structures such as bridge piers and dams.

Masonry cements conform to the requirements of ASTM C91. They are mixtures of portland cement, air-entraining additives, and supplemental materials selected for their ability to impart workability, plasticity, and water retention to masonry mortars. Because of manufacturing controls, the workability, strength, and color of masonry cements are maintained at a uniform level.

Special portland cements are special types of portland cement not covered by ASTM specifications.

Oil well cement is used for sealing oil wells. Generally, it must be slow-setting and resistant to high temperatures and pressures. The American Petroleum Institute Specification for Oil Well Cements (API Standard 10A) covers requirements for each of seven classes. Each class is applicable for use at a certain range of well depths. The petroleum industry also uses conventional types of portland cement together with suitable set-modifying admixtures.

Waterproofed portland cement is usually made by adding, during final grinding, a small amount of calcium, aluminum, or other stearate to portland cement clinker. It is available in either white or gray color.

Plastic cements are made by adding plasticizing agents up to 12 per cent by total volume to Type I or II cement during manufacturing. Plastic cements are commonly used for making mortar, plaster, and stucco.

AVAILABILITY OF CEMENTS

Some of the cements listed above may not be economically available in all sections of the country. Before specifying the type of portland cement, its availabity should be determined. For example, Type V cement is used mainly in western states and is seldom required in other areas.

Type I cement is generally carried in stock and is furnished if the type of cement is not specified. If a given type is not available, comparable results frequently may be obtained with one of the available types. For example, high-early-strength concrete can be made by using richer mixes (higher cement contents) of Type I portland cement. Also, the effects of heat of hydration may be minimized by using smaller lifts or artificial cooling.

21055

stewing. He is responsible to the chef. This job may be combined with that of chef or first cook.

Second cook (dinner cook): Prepares, cooks, and serves meats, vegetables, soups, sauces, and creamed dishes. He may operate the broiler and prepare special dishes.

First cook (working chef): Forecasts food consumption, plans menus, assists the cooks in preparing, cooking, and serving food. May take the place of the chef at times.

Pastry chef (baker): Bakes bread, rolls, muffins, and other hot breads; he may also be in charge of pastries and other dessert items. The term pastry chef is usually found in large establishments. The baker is his immediate assistant.

Chef: Plans meals; supervises and coordinates the work of all chefs, cooks, and other kitchen employees. The chef is responsible for the successful operation of the food production department. Since he is a manager, the term executive chef is often used.

It should be fully understood that the list above is not a complete one of all occupations in the food service industry. The descriptions are not intended to be complete. They merely indicate some of the responsibilities of key positions. It should also be noted that some establishments do not employ chefs. The food production manager, food production supervisor, and in some instances, the dietitian serve in much the same capacity as the chef.

For a complete listing of the many jobs in the food service industry refer to the *Occupational Outlook Handbook.*

2081

APPLICATION

Discuss portland cement, its history, manufacture, characteristics, and types.

Examine Type I and white portland cement samples.

Show film, From Mountains to Microns (see film list).

TEST OR DISCUSSION POINTS

1. What is the difference between "cement" and "concrete"?
2. Explain the difference between "concrete" and "mortar."
3. From what raw materials is portland cement made?
4. What is the volume of a bag of portland cement and how much does it weigh?
5. Explain how you would handle "warehouse pack."
6. Explain what is meant by hydration.
7. Is portland cement a brand or a type of cement?
8. What type of cement is most commonly used?
9. Are cements manufactured to meet particular specifications?
10. Which is correct terminology--a "cement sidewalk" or a "concrete sidewalk"?

MIXING WATER FOR CONCRETE

The principal purpose for using water with cement is to cause hydration of the cement. Additional water in excess of hydration requirements makes it possible to use more aggregates and thus produce a workable and economical mixture. Water ordinarily constitutes from 14 to 21 per cent (28 to 42 U.S. gal. per cubic yard) of the total volume of concrete.

As discussed later in this series, there is a definite relation between the amount of water used and the quality of the resulting concrete; too much water results in poor quality concrete. The amount of water must therefore be limited to produce concrete of the quality required for the job.

MIXING WATER FOR CONCRETE--HOW IMPURE CAN IT BE?

Almost any natural water that is drinkable and has no pronounced taste or odor is satisfactory as mixing water for making concrete. However, water suitable for making concrete may not necessarily be fit for drinking--even though many

specifications for construction work state that water used should be fit to drink. Tests should be made to be sure that the setting time of the cement paste is not adversely affected by impurities in mixing water. Excessive impurities may affect

21057

not only setting time, concrete strength, and volume stability, but may cause efflorescence, surface discoloration, and corrosion of steel. When water of unknown performance (containing impurities that would cause possible adverse effects) is considered for use, particularly on larger concrete jobs, it is good practice to make a strength test in which known acceptable water is used for comparison. Both 7- and 28-day strengths of test cylinders should be equal to strengths of at least 90 per cent of companion specimens made with known acceptable water.

Five typical analyses of city water supplies are shown in Table 1. These waters approximate the composition of water supplies for about 45 per cent of the cities over 20,000 population in the United States. Water from any of these sources is suitable for making concrete. If a water is of unknown performance but is comparable in analysis to any of the waters in the table, it is probably satisfactory for use in concrete.

Water containing less than 2,000 ppm (parts per million) of dissolved solids can generally be used satisfactorily for making concrete. Although concentrations exceeding this amount are not always harmful, they affect certain cements adversely. Where possible, high concentrations should be avoided. Water departments usually will furnish an analysis of the local water.

HOW IMPURITIES AFFECT MIXING WATER

A summary of the effects of certain common impurities in mixing water on the quality of plain concrete follows:

Carbonates and bicarbonates of sodium and potassium have different effects on the setting time of different cements. Sodium carbonate may cause very rapid setting; bicarbonates may either accelerate or retard the set. In large concentrations, these salts can materially reduce concrete strength. When the sum of these dissolved salts exceeds 1,000 ppm (0.1 per cent). tests for setting time and 28-day strengths should be made.

A high dissolved-solids content of a natural water is usually due to a high content of sodium chloride or sodium sulfate. Both can be tolerated in rather large quantities. Concentrations of 20,000 ppm of sodium chloride are generally tolerable. Mixing waters containing 10,000 ppm of sodium sulfate have been used satisfactorily.

Carbonates of calcium and magnesium are not very soluble in water. As a result, they do not affect the strength of concrete. Bicarbonates of calcium and magnesium are present in some municipal waters. Concentrations up to 400 ppm of bicarbonate ion in these forms are not considered harmful.

Magnesium sulfate and magnesium chloride can be present in high concentrations without harmful effects on strength. Good strengths have been obtained with concentrations up to 40,000 ppm. Calcium chloride can be used in concrete (except concrete containing aluminum or prestressing strand) in quantities up to 2 per cent by weight of cement to accelerate both hardening and strength gain.

21058

Natural groundwaters seldom contain more than 20 to 30 ppm of iron. However, acid mine waters may carry rather large quantities of iron. Iron salts in concentrations up to 40,000 ppm do not usually affect mortar strengths adversely.

Salts of manganese, tin, zinc, copper, and lead in mixing water may cause a significant reduction in strength and cause large variations in setting time. Of these, salts of zinc, copper, and lead are the most active. Other salts that are especially active as retarders include sodium iodate, sodium phosphate, sodium arsenate, and sodium borate. All of these salts can greatly retard both set and strength development when present in concentrations of a few tenths per cent by weight of cement. Generally, concentrations of these salts up to 500 ppm can be tolerated in mixing water. Another salt that may be detrimental to concrete is sodium sulfide; even 100 ppm warrants testing.

Seawater, containing up to 35,000 ppm (3.5 per cent) of salt, is generally suitable as mixing water for non-reinforced concrete. Although concrete made with seawater may have higher early strength than normal concrete, strengths at later ages (after 28 days) may be lower. This strength reduction can be prevented by reducing the water-cement ratio. Quality concrete can be made with seawater if the mix is properly adjusted.

If suitable fresh water is not available, seawater may be used for making reinforced concrete. Its use may increase the risk of corrosion; however, this risk is reduced if the reinforcement has sufficient cover and if the concrete is water-tight and contains an adequate amount of entrained air. Reinforced concrete structures made with seawater and exposed to marine environment should have a water-cement ratio of less than 5 gal. per bag and the reinforcement cover should be at least 3 in.

Seawater should not be used for making prestressed concrete in which the prestressing steel is in contact with the concrete.

Sand and gravel removed from seawater are sometimes used for making concrete. The amount of sea salt on aggregate is usually not more than about 1 per cent of the weight of mixing water. Such aggregates used with drinkable water contribute less salt to the mix than seawater does.

Acceptance of acid mixing water should be based on the concentration (in parts per million) of acids in the water. Occasionally, acceptance is based on the pH, which is a measure of the hydrogen ion concentration. The pH of neutral water is 7.0; values below 7.0 indicate acidity and those above 7.0, alkalinity. The pH value is an intensity index and is not the best measure of potential acid or basic reaction.

Generally, mixing waters containing hydrochloric, sulfuric, and other common inorganic acids in concentrations as high as 10,000 ppm have no adverse effect on concrete strength. Acid waters with pH values less than 3.0 may create handling problems and should be avoided.

21059

Waters having sodium hydroxide concentrations of 0.5 per cent by weight of cement do not greatly affect the concrete strength provided quick set is not induced. Higher concentrations, however, may reduce the strength.

Potassium hydroxide in concentrations up to 1.2 per cent by weight of cement has little effect on the concrete strength developed by some cements, but the same concentration when used with other cements may substantially reduce the 28-day strength.

Most waters carrying industrial waste have less than 4,000 ppm of total solids. When such water is used as mixing water in concrete, the reduction in compressive strength is generally not greater than about 10 per cent. Waste waters from tanneries, paint factories, coke plants, chemical and galvanizing plants, etc., may contain harmful impurities. It is best to test any waste water that contains even a few hundred parts per million of unusual solids.

A typical sewage may contain about 400 ppm of organic matter. After the sewage is diluted in a good disposal system, the concentration is reduced to about 20 ppm or less. This amount is too low to have any significant effect on concrete strength.

Small amounts of sugar, as little as 0.03 to 0.15 per cent by weight of cement, usually retard the setting of cement. The upper limit of this range varies with different cements. The 7-day strength may be reduced while the 28-day strength may be improved. When the amount of sugar is increased to about 0.20 per cent by weight of cement, the set is usually accelerated. Sugar in quantities of 0.25 per cent or more by weight of cement may cause rapid setting and a substantial reduction in 28-day strength.

Less than 500 ppm of sugar in mix water has generally no adverse effect on the concrete strength, but if the concentration exceeds this amount, tests for setting time and concrete strength should be made.

About 2,000 ppm of suspended clay or fine rock particles may be tolerated in mixing water. Higher amounts may not affect strength but may influence other properties of some concrete mixtures. Muddy water should remain in settling basins before use to reduce the amount of silt and clay added to the mix.

Various kinds of oil are occasionally present in mixing water. Mineral (petroleum) oil, not mixed with animal or vegetable oils, probably has less effect on strength development than other oils. However, mineral oil in concentrations greater than 2 per cent by weight of cement may reduce the concrete strength by more than 20 per cent.

Algae present in mixing water may cause excessive reduction in strength either by combining with the cement to reduce bond or by causing a large amount of air to be entrained in the concrete. Algae may also be present on aggregates, in which case the bond between the aggregate and cement paste is reduced.

21060

APPLICATION

Discuss mixing water for concrete. Obtain or assign someone to obtain analysis of local water(s). This can be compared with analyses of city water supplies that are known to be satisfactory for use in concrete.

TEST OR DISCUSSION POINTS

1. What is the purpose of mixing water?
2. Why is more water used than necessary for its principal purpose?
3. What is a good rule for determining whether water is satisfactory as mixing water for making concrete?
4. If water of unknown performance is to be used for concrete, explain how to determine whether it will be acceptable.
5. What are some of the effects impurities in the miximg water may have on concrete?
6. Do you think seawater should be used in concrete?
7. After what process would sewage water be usable?
8. What effect would algae have if present in mixing water?

AGGREGATES FOR CONCRETE

Sand, gravel, and crushed stone are the aggregates most commonly used in concrete to provide volume at low cost. Since aggregates make up about 60 to 80 per cent of the volume of concrete, they can be called a filler material.

The selection of aggregates is of particular importance in making concrete. Their characteristics greatly influence the properties, mix proportions, and economy. They should consist of particles having adequate strength and resistance to exposure conditions. They should not contain materials having harmful effects such as dirt, clay, coal, or organic matter. They should also be graded in size to secure the best economy from the paste. Aggregates are generally classified as fine and coarse.

CHARACTERISTICS OF AGGREGATES

Basically, good aggregates must have certain characteristics to give workable, strong, durable, and economical concrete. These characteristics include abrasion resistance, resistance to freezing and thawing, compressive strength, chemical stability, and good particle shape and surface texture.

Abrasion resistance of an aggregate is often used as a general index of aggregate quality. It is essential when the aggregate is used in concrete subject to abrasion, as in floors and pavements.

Resistance to freezing and thawing is important when aggregates are used in exposed concrete. The freeze-thaw resistance of an aggregate is related to its porosity, absorption, and pore structure. If an aggregate particle absorbs so much water that insufficient pore space is available to accommodate water expansion that occurs during freezing, it may be vulnerable to freezing.

Compressive strength of an aggregate is its resistance to compressive forces.

Chemical stability of an aggregate indicates that the aggregate will not react chemically with cement or be affected chemically by other external influences. In some areas, aggregates with certain chemical constituents react with alkalies in cement. This alkali-aggregate reaction may cause abnormal expansion and map-cracking of concrete.

Particle shape and surface texture of an aggregate influence the properties of fresh concrete more than they affect the properties of hardened concrete. Rough texture or flat and elongated particles require more cement paste to produce

21062

298

workable concrete than do rounded or cubical aggregates. However, crushed and uncrushed aggregates generally give essentially the same strength for the same cement content.

Coarse aggregate particles should be cubical in shape and free of excessive amounts of flat and elongated pieces. Long, slivery aggregate pieces should be avoided, or at least limited to 15 per cent by weight of the total aggregate. This requirement is equally important for fine aggregate, since sand made by crushing stone often consists of angular particles. When manufactured sand is used for fine aggregate in concrete, care should be taken to avoid materials having an abundance of thin, slivery particles, especially if the amount of water required to make a cubic yard of concrete is considerably greater than if well-graded particles were used.

GOOD AGGREGATES ESSENTIAL

Aggregates that are hard and durable are best suited for use in concrete. Aggregates that are soft and flaky and will wear away rapidly through exposure to weather generally are unsatisfactory. Weak, friable or laminated aggregate particles are undesirable. Shale, stones laminated with shale, and most cherts are to be avoided.

CLEAN AGGREGATES DESIRABLE

In addition to being hard and durable, the best aggregates are clean and free of fine dust, loam, silt, clay, or vegetable matter. These materials are objectionable because they prevent the cement paste from binding the aggregate particles, thereby reducing the strength of the concrete. Concrete made with dirty aggregates hardens slowly or may never harden enough to serve its intended use.

TESTING AGGREGATES FOR QUALITY

If it is necessary to use aggregates of unknown quality, they should be carefully examined and tested to make sure they are suitable for making concrete.

The silt test is used to detect the presence of extremely fine material. The colorimetric test is used to detect the presence of harmful amounts of vegetable matter.

In making the silt test, use an ordinary quart milk bottle or quart fruit jar (Fig. 9). Fill the container to a depth of 2 in. with a representative sample of dry sand to be tested. Add water until the bottle or jar is about three-fourths full. Shake vigorously for 1 minute. The last few shakes should be in a sidewise direction to level off the sand. Allow the jar to stand for an hour. During this time any silt present will be deposited in a layer above the sand. If the layer is more than 1/8 in. thick, the sand from which the sample is taken is not satisfactory for concrete work unless the excess silt is removed. This may be done by washing.

21063

Fig. 9 Silt test.

In making the colorimetric test, an ordinary 12-oz. prescription bottle, such as druggists or physicians use, is filled to the 4-1/2 oz. mark with a sample of the sand (Fig. 10). To this is added a 3 per cent solution of caustic soda which is made by dissolving 1 oz. of sodium hydroxide (household lye) in a quart of water, preferably distilled. The solution should be kept in a glass bottle tightly closed with a rubber stopper.

Handling sodium hydroxide with moist hands may result in serious burns. Do not spill the solution, as it is highly injurious to clothing, leather, and most other materials.

As soon as the solution of sodium hydroxide is added to the sand, shake the contents of the bottle thoroughly and then allow it to stand for 24 hours. The color of the liquid will indicate whether the sand contains vegetable matter. A colorless liquid indicates a clean sand free from vegetable matter. A straw-colored solution indicates some vegetable matter but not enough to be seriously objectionable. Darker colors mean that the sand contains injurious amounts and should not be used unless it is washed and tested again.

Fig. 10. Colorimetric test.

FINE AGGREGATES

Fine aggregates are particles 1/4 in. and less in size. Natural and manufactured sands are the most common. They have particles ranging from 1/4 in. down to some that will pass through a sieve having 100 openings to the inch.

COARSE AGGREGATES

Coarse aggregates are usually gravel or crushed stone. Sizes range from 1/4 in. up to the maximum size permissible for the job.

BANK-RUN AND COMMERCIALLY RECOMBINED AGGREGATES

Bank-run material is aggregate that is used as taken from the quarry or gravel pit. The natural mixture of fine and coarse aggregates as taken from a gravel bank or crusher usually does not make the most economical concrete unless it is first screened to separate the fine material from the coarse and then recom-

2082

bined in the correct proportions. Most gravel banks contain too much sand in proportion to coarse material. More cement paste is required to produce concrete of a given quality when there is a high proportion of fine aggregate.

When using bank-run material, it is generally advisable to screen the material to separate it into fine and coarse aggregates. Some commercial firms also sell a mixed aggregate. Sand and gravel are separated and then recombined into the correct proportions for concrete.

Frequently, these aggregates are not clean enough for use until they are washed to remove silt, clay, or other materials detrimental to good concrete. Since clean aggregates are essential to quality concrete, washing is well worth the effort.

If concrete aggregates are sold by weight in your locality, you may assume, for estimating purposes, that a ton contains approximately 20 to 22 cu.ft. of sand, crushed stone, or gravel.

LIGHTWEIGHT AGGREGATES

The most commonly used aggregates, such as sand, gravel, crushed stone, and air-cooled blast-furnace slag, produce normal-weight concrete, i.e., concrete weighing from about 140 to 160 lb. per cubic foot. Expanded shale, clay, slate, and slag are used as aggregates to produce structural lightweight concretes having unit weights ranging from about 85 to 115 lb. per cubic foot. Other lightweight materials, such as cinders, pumice, scoria, perlite, vermiculite, and diatomite, are used to produce insulating concretes weighing about 20 to 70 lb. per cubic foot.

HEAVYWEIGHT AGGREGATES

Heavyweight materials, such as barytes, limonite, magnetite, ilmenite, iron, and steel particles, are used for producing heavyweight concrete.

GRADATION OF AGGREGATES

The photographs show how well-graded aggregates look before and after being separated into various sizes.

Fig. 11. This is how a well-graded coarse aggregate looks before being separated. Note how the smaller pieces fit among larger ones in the mixed aggregate.

21065

Fig. 12. This is how a well-graded coarse aggregate looks after being separated into three sizes. From left to right: 1/4 to 3/8 in., 3/8 to 3/4 in., 3/4 to 1-1/2 in.

Fig. 13. Sample of well-graded sand before and after separation into various sizes. Particles vary from dust to those just passing the No. 4 sieve (approximately 1/4 in.).

In making good concrete, each particle of aggregate, regardless of size, must be completely surrounded by paste. It is important that fine and coarse aggregates be proportioned so that the finer particles will fill the spaces between the larger ones. This results in the most economical use of cement paste for filling the voids and binding together the aggregate particles.

To demonstrate this concept, a simple though crude method can be used. Obtain three transparent containers of equal capacity and place the same amount of water (representing a selected quality of cement paste) in each. Fill to approximately one-fourth capacity. Now add as much coarse aggregate to one container as the cement paste (water) will cover. Do the same with fine aggregate in the second container. To the last container add a combined or proper gradation of aggregates. Note that the same amount of cement paste (water) covers the

Fig. 14. Sample of sand which lacks particles larger than 1/16 in. (above). Sample separated (below) into four sizes. More cement is required when sand is fine. This is not a good concrete sand.

surface area of a greater volume of material in the last container. This shows that economy is obtained by proper gradation of aggregates. Also, it demonstrates that the cement paste requirement for concrete is proportional to the void content of the combined aggregates. It also shows that the amount of concrete (of a given quality) that can be obtained from a bag of cement depends on the filler material.

DETERMINING MAXIMUM SIZE OF COARSE AGGREGATE

As previously illustrated, the larger the coarse aggregate the less paste necessary. Hence, more concrete is obtained per bag of cement. This means that, generally, the most economical mix is obtained by using the largest coarse aggregate practical for the job. The maximum size generally depends on the size and shape of concrete members and the amount and distribution of reinforcing steel.

In general, the maximum size of aggregate should not exceed:

1. One-fifth the dimension of non-reinforced members,

2. Three-fourths the clear spacing between reinforcing bars or between reinforcing bars and forms, or

3. One-third the depth of non-reinforced slabs on grade.

The common maximum sizes are 3/8, 1/2, 3/4, 1, 1-1/2, and 2 in.

HANDLING AND STORING AGGREGATES

Aggregates should be handled and stored to prevent segregation of sizes and contamination with harmful materials. Stockpiles should be built up in layers of uniform thickness and not in cone-shaped piles, which result in segregation of sizes. Fine aggregates that are damp have less tendency to segregate than dry material. Material should be removed from stockpiles in approximately horizontal layers to minimize segregation.

21067

TERMINOLOGY

1. Aggregate - Term used in construction for crushed rock, gravel, sand or other materials used with cement, lime and asphalt to make concrete, plaster, etc.

2. Sand - The fine granular material (usually less than 1/4" in diameter) resulting from natural disintegration of rock, or the crushing of friable sandstone rocks.

3. Gravel - The coarse granular material, larger than sand, resulting from the natural erosion of rock.

4. Crushed Gravel - The product resulting from the artificial crushing of gravel with substantially all fragments having at least one face resulting from fracture.

5. Crushed Stone - The product resulting from the artificial crushing of rock, usually from a quarry, substantially all faces of which have resulted from the operation.

6. Crusher Run - The total unscreened product of a stone crusher.

7. Mesh - The number of openings per linear inch in a sieve.

8. Screen - In laboratory work, an apparatus in which the apertures are circular, for separating sizes of material.

9. Sieve - In laboratory work, an apparatus in which the aperatures are square, for separating sizes of material.

10. Grading Analysis - Made by separating a sample into sizes by the use of specified sieves and weighing the amount retained on each sieve. Results of this test are expressed most often as the percent passing each of the designated sieves. In the case of concrete aggregate, an empirical factor, finus modulus, is obtained by adding the total cumulative percentages of a sample of the aggregate retained on each of a specified series of sieves, and dividing the sum by 100.
The sieves are as used - No's. 100, 50, 30, 16, 8, 4, 3/8, 3/4, 1-1/2 and larger, increasing in the ratio of 2 to 1.

11. Saturated Surface Dry Aggregate - This is aggregate which has absorbed all the water it is capable of absorbing but has no free moisture on the surface.

12. Specific Gravity - In the case of concrete aggregate, is usually expressed as the ratio of the weight in air of a saturated surface dry sample to the weight of an equal volume of water.

13. Absorption - This is expressed in percent, and is found by dividing the difference between saturated surface dry weight and oven dry weight by the oven dry weight and multiplying by 100.

21068

14. Unit Weight - In the case of concrete, is the weight of a stated volume, usually 1 cubic foot, of fresh compacted concrete; in the case of aggregate, is the weight of a stated volume of loose dry or moist material, or the weight of compacted dry or moist material.

15. Mortar Making Properties of Sand - This is determined by making mortars using the sand under test and standard Ottowa sand, curing for 7 days, then testing for compressive strength. The strength of the sand under test is expressed as the ratio of the 7 day compressive strength of the tested sand to the 7 day strength of the standard sand.

16. Organic Impurities - In sand can be discovered by placing a sample of the sand in 3% solution of sodium hydroxide. If there are impurities in the sand, the solution will darken in color.

17. Silt and Clay - Is that material in a sand that will be lost by decantation. The amount of loss by decantation is equivalent to that which would pass a No. 270 sieve. In the case of USBR specifications, sediment is interpreted to mean the passing 200 mesh.

18. Sand Equivalent - This test is intended to serve as a rapid field test to show the relative proportion of detrimental fine dust or clay-like material in soils or fine aggregate.

19. Cleanness Value - This test is intended to serve as a rapid field test to show the relative proportion of detrimental fine dust or clay-like material in coarse aggregate.

20. Soundness of Aggregates - Is determined by alternate wetting with sodium sulfate (or magnesium sulfate) and drying in an oven with the aggregate under test. After 5 such cycles the sample is washed, dried and weighed. The sample before test is 100% retained on a stated sieve. The soundness is, by ASTM and USBR method, expressed as the loss in percent passing a stated sieve. Using the State of California method, the soundness is expressed as the loss in percent passing the next smaller than the stated sieve.

21. Tests for Abrasion - These are made in a machine known as the Los Angeles Rattler. A weighted sample is placed in the barrel of this machine and revolved a stated number of times, removed and sieved on a No. 12 sieve. The difference between the original weight and the final weight, expressed as a percentage of the original weight of the test sample is the Loss by Abrasion.

21069

APPLICATION

Lead discussion covering aggregates.
Show aggregate samples.
Show, explain, and demonstrate laboratory sieves.
Demonstrate silt test.
Demonstrate colorimetric test.

TEST OR DISCUSSION POINTS

1. Why are aggregates referred to as filler material?
2. What are the two classifications of aggregates?
3. What are some of the characteristics of a good aggregate?
4. What types of aggregates should be avoided?
5. What effect will dirty aggregates have on the strength of concrete?
6. How would you test sand for silt and organic matter?
7. What is a colorimetric test and how is it conducted?
8. Define "fine aggregates" and "coarse aggregates."
9. Why is bank-run gravel seldom suitable for concrete work?
10. How can bank-run gravel be made usable?
11. About how many cubic feet are in a ton of sand? Crushed stone? Gravel?
12. Why are lightweight aggregates used for certain jobs?
13. Why does the proportion of fine and coarse aggregates affect the concrete yield--the amount of concrete that can be obtained from a bag of cement and a fixed proportion of water?
14. Explain "void content" as it applies to concrete aggregates.
15. What factors determine the maximum size of aggregate that can be used?
16. How should aggregates be stockpiled on the job?

TOOLS AND MATERIALS

For silt test: quart milk bottle or quart fruit jar, dry sand, and water.
For colorimetric test: three 12-oz. prescription bottles, sodium hydroxide (household lye), water, rubber gloves, sand with no organic matter, sand with a small amount of organic matter, sand with a large amount of organic matter.
Aggregates: fine, coarse, bank-run and recombined, lightweight.
Set of laboratory sieves.

REFERENCE MATERIALS

ASTM Designation C33, "Standard Specifications for Concrete Aggregates."

21070

Fresh concrete containing entrained air is cohesive and looks and feels "fatty." The billions of disconnected air bubbles reduce segregation and bleeding (separation of the water from the paste) of freshly mixed concrete. This reduction in segregation and bleeding results in a more durable concrete. The air bubbles buoy up the aggregates and cement and thus reduce their rate of settlement toward the bottom of the placed concrete. Bleeding is retarded because water cannot readily pass through the minute bubbles. Air-entrained concrete can also be finished sooner than ordinary concrete. However, do not take the absence of bleeding water as an indication that the concrete is setting and attempt to finish too soon.

EFFECT OF ENTRAINED AIR ON PROPERTIES OF HARDENED CONCRETE

The resistance of concrete to freezing and thawing, as well as to various de-icing chemicals, is significantly improved by the use of entrained air. This improvement in freeze-thaw resistance is particularly desirable if the concrete is saturated with water. As water freezes, it expands (up to 9 percent), producing pressures that can rupture the concrete and cause scaling. Because the entrained air bubbles are round, they never completely fill with water. As water freezes, its expansion is relieved by the remaining air space in the bubble, thus preventing damage to the concrete. The bubbles or air voids continue to serve their purpose during repeated cycles of freezing and thawing. The resistance of air-entrained concrete to freeze-thaw action is improved several hundred per cent over concrete that contains no entrained air.

Fig. 16. Compare the results of freeze-thaw action on these test specimens containing varying amounts of air. Note the excellent resistance of the concrete containing adequate entrained air.

De-icing chemicals used for snow and ice removal can cause serious surface scaling. Entrained air prevents salt scaling and is recommended for all

21072

concretes that come in direct or indirect contact with de-icing chemicals. Indirect application of de-icers can be caused in various ways, such as by drippings from the underside of vehicles.

Concrete mixes that have been properly adjusted for the addition of air entrainment will have little if any loss of strength when compared to a similar non-air-entrained concrete. Adjustment of both water and sand contents is necessary to maintain the same strength. The water content for air-entrained concrete will be 3 to 5 gal. less per cubic yard than for non-air-entrained concrete having the same slump. The percentage of sand in air-entrained concrete can and should be reduced. A 3 to 6 per cent reduction of sand content is possible without any loss of workability. If no adjustment is made in the sand content, lower strengths result because of the increased yield.

Abrasion resistance of air-entrained concrete is about the same as that of non-air-entrained concrete of the same compressive strength. Compressive strength is one way to estimate abrasion resistance of concrete. Abrasion resistance usually increases as the compressive strength increases.

Watertightness of air-entrained concrete is superior to that of non-air-entrained concrete. For a given cement factor, air-entrained concretes generally have lower water-cement ratios and hence are more watertight. Air-entrained concrete should be used where watertightness is desired.

AIR-ENTRAINING MATERIALS

The entrainment of air in concrete can be accomplished by adding an air-entraining admixture at the mixer, by using an air-entraining cement, or by a combination of both methods.

Many cement manufacturers market portland cement containing air-entraining agents that are interground with the cement during manufacture. Such cements are identified on the bag.

Variations in air content can be expected with variations in aggregate type and size, proportions and gradation, mixing time, temperature, and slump. With air-entraining admixtures, the volume of entrained air can be adjusted more readily to meet job conditions by changing the amount of admixture.

Each of the methods described above has certain advantages. The use of air-entraining cement avoids the problem of adding an extra ingredient at the mixer. On jobs where careful control is not practical, air-entraining cements are especially useful since they eliminate the possibility of human or mechanical error when adding an admixture during batching. Regardless of which method is used, adequate control is required to ensure proper air content at all times.

21073

Recommended Amounts of Entrained Air

Per Cent Air	Maximum Size Aggregate
5 ± 1	1-1/2", 2", or 2-1/2"
6 ± 1	3/4" or 1"
7-1/2 ± 1	3/8" or 1/2"

Mixes should be designed to contain more air than desired when the concrete is placed. A good rule of thumb is to use 6 percent plus or minus 1 percent.

Aggregate type, gradation, size, and mix proportions affect the percentage of air required. There is little change in air content when the maximum size of aggregate is increased above 1-1/2 in. For aggregate sizes smaller than 1-1/2 in., the air content increases sharply as the aggregate size decreases.

FACTORS AFFECTING AIR CONTENT

In addition to aggregate gradation and mix proportions, there are other factors that affect the percentage of entrained air.

One factor is the fine aggregate content. Increasing the amount of fine aggregate results in a need for more entrained air.

Other factors are slump and vibration. Both slump and vibration affect the amount of air retained in the finished concrete. The desired air content can be maintained as long as the slump does not exceed 6 in. With further increases in slump, air content is lost rapidly.

The duration of vibration also affects air content. A normal amount of vibration does not materially affect the amount of entrained air. However, prolonged vibration of concrete should be avoided. For most concrete, the desired consolidation should be obtained with 5 to 15 seconds of vibration. If vibration is properly applied, little of the intentionally entrained air is lost.

A third factor is concrete temperature. Less air is entrained as the temperature of the concrete increases. The effect of temperature is especially important during hot-weather concreting when concrete may be quite warm. A decrease in air content can be offset, if necessary, by increasing the quantity of air-entraining admixture.

Mixing action also affects the amount of entrained air. This is especially important for ready mixed concrete. The amount of entrained air varies with the type and condition of the mixer, the amount of concrete being mixed, and the rate of mixing.

MEASUREMENT OF AIR CONTENT

Tests for air content of fresh concrete should be made during construction for routine control purposes. Because of the effects of mixing and vibration, samples for air content should be taken preferably from concrete that has been placed and consolidated.

APPLICATION

Conduct discussion of air-entrained concrete.
Show sample of air-entraining admixture. Show bag of Type I-A cement.
Show slide 10 from Mr. Quality Concrete slide set.

TEST OR DISCUSSION POINTS

1. What is the principal reason for using intentionally entrained air in concrete?
2. Explain the effect of entrained air on the properties of fresh concrete.
3. How and why does air entrainment effect workability?
4. How does air entrainment affect the freeze-thaw resistance of concrete? How is this accomplished?
5. Under what conditions of climate would air-entrained concrete be especially desirable?
6. What are the two methods used to obtain air entrainment in concrete?
7. What is the rule of thumb for determining the percentage of air entrainment required in concrete?

TOOLS AND MATERIALS

Sample of air-entraining admixture
Bag of Type I-A cement
Mr. Quality Concrete slide set
Pocket-size air indicator

21075

ADMIXTURES FOR CONCRETE

Occasionally an admixture will be used in concrete. The inspector should determine the purpose of its use and familiarize himself with the characteristics of the particular admixture proposed and with expected results.

There are literally dozens of admixtures available, but most fall into one or more of the following categories:

1. Air-entraining admixtures.
2. Water-reducing admixtures
3. Retarding admixtures.
4. Accelerating admixtures.
5. Pozzolans.
6. Workability agents.
7. Miscellaneous, such as dampproofing and permeability-reducing agents, grouting agents, and gas-forming agents.

The most commonly used admixtures fall into the first four categories. Some admixtures perform dual functions. For example, air-entraining agents reduce water demand also for a given slump. Some water-reducers are also set-retarders.

In any structure where prestressed concrete is used, it is of the utmost importance that no admixture containing chlorides be permitted. Corrosion of prestressed steel can result from the use of even minor amounts of chloride. Chloride-containing admixtures should not be used in concrete in these structures even though it may not be in direct contact with the prestressed steel - it should be used, for instance, in slabs placed on prestressed girders.

Many specifications require admixtures to perform certain functions and limit their effect on certain concrete properties. The inspector should assure himself that the admixture being used is, in fact, the one specified, and also that it conforms to the specification requirements. Sometimes brand names are specified, sometimes tests are required either in the laboratory or in the field, and sometimes acceptance can be based on certification by the supplier or manufacturer.

Some combinations of admixtures are incompatible, that is, if added simultaneously to water, for example, will form a precipitate and neither may be very effective. When two or more admixtures are being used, the inspector should seek advice from a technical representative, or someone familiar with the products to determine if any special measures must be taken, or if one or the other products should be substituted by another.

Dosage is important for over-doses of many admixtures may have serious detrimental effects. The inspector should determine dosages recommended by the manufacturer, paying close attention to rates. Some are added on a "per sack of cement" basis; others might be added on a "per cubic yard of concrete" basis. Some admixtures increase the drying shrinkage of concrete, and if concrete shrinkage is a critical factor, it should be considered when the use of an admixture is being considered.

21076

Air-entraining Agents

Air-entraining agents, when used in proper amounts, increase the durability of all concrete. When it is used to produce frost resistant concrete, an adequate amount must be used, depending on the size of the coarse aggregate. Because air entrainment reduces compressive strength and much concrete is "bought" on a strength basis, there is a tendency to use as little air as possible. It is much better to put in sufficient air to provide needed frost protection and risk slightly lower strength than it is to reduce the air content to a point where adequate frost protection would not be achieved, merely to preserve strength. Air-entraining agents are usually in liquid form and should, as should water-reducers and set-retarders, beadded in liquid form to the stream of mixing water as it enters the mixer by means of a reliable injector. The specifications may describe the way admixtures are to be added to the concrete. Non-uniformity of results have often been traced to faulty methods of adding the admixture to the concrete.

The cost of additional portland cement to offset a minor strength loss because of the use of air-entrained concrete is normally an insignificant part of the total cost of a structure -- in the case of a typical highway bridge, for example, about 1/1000th of the total cost of the structure.

Air-entraining agents improve workability and finishability of concrete, reduce water content, reduce bleeding, and help prevent segregation. They are often used for these purposes in lesser amounts than are necessary for freeze-thaw protection. In any event, frequent checks on air content should be made on the fresh concrete for purposes of control. A pressure type meter can be used for ordinary aggregates, but a volumetric type is recommended when lightweight or porous aggregates are used. A low cost pocket air meter is available for making quick check tests, but should be used in conjunction with a meter requiring larger samples. If a mix has not been designed for entrained air, adjustments are usually made to maintain the yield and to avoid "sticky" mixes which are difficult to finish.

Water-Reducers and Set-Retarders

Many water-reducing agents also retard the setting of the concrete. Retardation up to four to six hours can be attained with normal dosages. While the set of the cement is retarded, there may be loss of slump with time just as if the retarder were not used. The amount of some admixtures needed to retard set for a specified period depends upon atmospheric conditions that prevail and the temperature of the concrete. Usually, the higher the air temperature and concrete temperature, the larger the dosage required for a given retardation. Some of these materials entrain five percent or more air. Adding a double dosage may double air content, resulting in substantial strength reductions and sticky concrete.

Some water-reducers do not retard the setting of the concrete, either by their basic nature or because some accelerating agent has been added to restore normal setting time. Some, depending on their chemistry, may substantially increase shrinkage.

21077

Some admixtures have been known to react differently with different cements. When any unusual or unexpected results occur, their use should be discontinued until the reason, or reasons for the unexpected results are determined. Pre-testing with job materials under job conditions of placement, temperature, etc., is recommended wherever practicable.

Set Accelerators

One of the most common set accelerators used in concrete is calcium chloride. Normally, the largest amount used is two pounds per sack of cement. It should be dissolved in water (adding the flakes or pellets to the water rather than adding the water to the calcium chloride) before adding to the concrete. Because of possible adverse effects, the decision to use calcium chloride should receive careful considerations.

Possible detrimental effects are:

1. Incompatible with certain other admixtures.
2. Contribute to corrosion problems, especially when aluminum and steel are imbedded in the same concrete.
3. May cause rapid stiffening of concrete which would be undesirable.
4. May reduce resistance of concrete to sulfate attack.
5. May increase expansion due to alkali-aggregate reaction.
6. May contribute to discoloration of slabs.

Often, high early strengths can be obtained without the use of calcium chloride, such as using extra cement, or Type III cement, or arranging to apply heat to the concrete (steam curing, for example). Since the decision to use calcium chloride may be made on short notice, the inspector should be familiar with the limitations and possible detrimental effects, and know beforehand what he should or could do in each case. In no case should it be used in prestressed concrete, whether the chloride-containing concrete will be in contact with the prestressing steel or not.

The accelerating agent in water-reducers may be calcium chloride and the proposed water-reducer should be examined for this if it is to be used with prestressed concrete.

Pozzolans

A material which is sometimes used as an admixture as well as for other purposes is called a pozzolan.

ASTM C219 defines a pozzolan as "a siliceous or siliceous and aluminous material, which in itself possesses little or no cementitious value but will, in finely divided form and in the presence of moisture, chemically react with calcium hydroxide at ordinary temperatures to form compounds possessing cementitious properties." A number of natural materials such as diatomaceous earth, opaline cherts and shales, tuffs and pumicites, and some artificial materials such as fly ash are used as pozzolans. Since the properties of pozzolans may vary widely, acceptance tests should be made before they are used. ASTM specifications and test methods for natural pozzolans (C402) and fly ash (C350 and C311) cover their use as admixtures in concrete.

Pozzolanic materials are sometimes used in concrete to help control internal temperatures. In massive structures such as dams, high temperatures can occur due to slow loss of heat generated during hydration. These temperatures can be minimized by using Type II, IV, V, IS or IP portland cement, lowering the temperature of the mixing water and aggregate, or using pozzolanic admixtures. Frequently, combinations of these three methods are used.

Some pozzolans are used as admixtures in order to reduce or eliminate potential expansion from alkali-reactive aggregates. Where reactive aggregates are to be used in concrete, for lack of non-reactive aggregates, a low-alkali cement or a proven pozzolan may be used to counteract expansion.

Fly ash is sometimes used as a pozzolanic admixture. It is a finely divided residue that results from the combustion of powdered coal. Generally it is not a uniform product and may contain varying amounts of carbon, silica, alkalies, sulfur and other components. Excessive amounts of some of these components may adversely affect the strength and durability of concrete.

Pozzolans vary considerably in their effect on concrete mixes. Before one is approved for use on a concrete job, it should be tested in combination with the cement and aggregates to ascertain its suitability with regard to water requirements, strength development, shrinkage, heat of hydration, durability, or other special properties.

Workability Agents

Fresh concrete is sometimes harsh due to certain aggregate characteristics such as particle shape and improper grading, or faulty mix proportions. Under these conditions, improved workability may be necessary, especially if the concrete requires a troweled finish. Improved workability is also important for concrete placed in heavily reinforced members, or placed by pumping or tremie methods. Frequently, increasing the cement content or the amount of fine aggregate will give the desired workability.

One of the best workability agents is an air-entraining admixture. Entrained air acts like a "lubricant" and is especially effective in improving the workability of lean, harsh mixtures.

Organic or finely divided materials are also sometimes used to improve the ease with which concrete can be placed and finished.

Some organic materials, when added to concrete of a given water content, will increase the slump. The composition of these compounds may be similar to that of water-reducing and retarding admixtures. These workability agents may also entrain air.

Finely divided materials are also used as admixtures to improve the workability of mixes deficient in material passing the No. 50 sieve. Some of these materials are relatively inert chemically while others are pozzolanic. When they are added to mixes that are not deficient in fines, additional water is generally required to maintain a given workability. This may reduce the strength, increase the drying shrinkage and adversely affect other properties of concrete. The use of pozzolans as cement replacements, however, can substantially reduce the early strength of concrete, especially during the first 28 days. Because of the slow pozzolanic action, prolonged continuous wet curing must be provided.

21079

Fly ash and natural pozzolans used as workability agents should conform to ASTM C350 or C402. These specifications warn that replacement of a portion of the portland cement by fly ash or a natural pozzolan may reduce the early strength of concrete and tend to reduce the amount of entrained air in concrete. Consequently, a greater amount of air-entraining admixture is generally required to obtain the recommended air content in concrete that contains fly ash or other pozzolans.

Other Types

Gas forming agents usually containing aluminum powder, are sometimes used to cause expansion of a plastic mortar or cement-water paste. Certain agents are known to react differently with different cements. Some field testing of the actual ingredients proposed for the work may be helpful in securing the desired results. Usually very small quantities are used so care must be taken to insure adequate dispersion in the mix. The aluminum reacts with the alkaline constituents in cement to form hydrogen gas bubbles. Some grouting admixtures contain other metals with chemicals to promote oxidation which causes an increase in the volume of the grout.

Admixtures known as permeability-reducing agents are usually either water-repellents or pozzolanic materials. They may reduce the permeability of concretes that have low cement contents and/or a deficiency of fines in the aggregate. However, their use in well-proportioned mixes may increase the mixing water required, resulting in increased rather than reduced permeability.

Dampproofing admixtures, usually water-repellent materials, are sometimes used to reduce the capillary flow of moisture through concrete that is in contact with water or damp earth. Many so-called dampproofers are not effective, especially when used in concretes that are in contact with water under pressure.

Inhibitors may be corrosion inhibitors or agents, such as pozzolans, which inhibit alkali-aggregate reaction. It is suggested that when agents of this nature are proposed, technical advice from someone who has knowledge of the products be consulted. This would apply to germicidal, fungicidal, and insecticidal agents as well.

Coloring agents are fairly commonly used in concrete. Some cause strength reduction and reduce the amount of air entrained if an air-entraining agent is also being employed. Usually, inorganic type pigments for coloring concrete are added in amounts of 2 to 10% of the weight of the cement; some much less. Often, when colored concrete is specified, a white cement is also specified to produce lighter colors. The specifications should be consulted and trial mixes are suggested whenever colored concrete is to be used.

HOW TO ESTIMATE CONCRETE FOR A JOB

The unit of measure for concrete is the cubic yard, which contains 27 cu.ft. Ready mixed concrete is sold by the cubic yard. Concrete produced on the job is also figured by the cubic yard. To determine the amount of concrete needed, find the volume in cubic feet of the area to be concreted and divide this figure by 27. The following formula can be used to determine the amount of concrete needed for any square or rectangular area:

$$\text{Cubic yards of concrete} = \frac{\text{width in feet X length in feet X thickness in feet}}{27}$$

For example, a 4-in.- thick floor for a 30x60-ft. building would require:

$$\frac{30 \text{ X } 60 \text{ X } 1/3}{27} = 22.22 \text{ cu.yd. of concrete.}$$

The amount of concrete determined by the above formula does not allow for waste or slight variations in concrete thickness. An additional 5 to 10 per cent will be needed to cover waste and other unforeseen factors.

Note: The thickness dimension must be changed to feet or parts of a foot. The fractional part of a foot was used in the example. However, the decimal part may be used instead. Table 10 gives both the fractional and decimal parts of a foot for several common thickness dimensions.

Table 10. How to Change Thickness in Inches to Fractions and Decimal Parts of a Foot for Use in Calculating Quantities of Concrete

Inches	Fractional part of foot	Decimal part of foot
4	4/12 or 1/3	0.33
5	5/12	0.42
6	6/12 or 1/2	0.50
7	7/12	0.58
8	8/12 or 2/3	0.67
10	10/12 or 5/6	0.83
12	1	1.00

21082

MATERIALS REQUIRED FOR JOB BATCHING

When concrete is job batched, the quantities of materials (cement, fine and coarse aggregate) must be figured separately for each cubic yard of concrete needed. Table 11 shows the number of bags of portland cement, cubic feet of fine aggregate, and cubic feet of coarse aggregate required to produce 1 cu.yd. or 27 cu.ft. of mixed concrete for the different suggested trial mixes. The example shows how to compute amounts of materials needed.

Table 11. Materials Needed per Cubic Yard of Concrete Made with Separated Aggregates

Suggested mixtures for 1 bag trial batches*			Materials per cu.yd. of concrete				
Cement,	Aggregates		Cement,	Aggregates			
	Fine,	Coarse,		Fine		Coarse	
bags**	cu.ft.	cu.ft.	bags	cu.ft.	lb.	cu.ft.	lb.
With 3/4-in. maximum size aggregate							
1	2	2-1/4	7-3/4	17	1550	19.5	1950
With 1-in. maximum size aggregate							
1	2-1/4	3	6-1/4	15.5	1400	21	2100
With 1-1/2-in. maximum size aggregate (preferred mix)							
1	2-1/2	3-1/2	6	16.5	1500	23	2300
With 1-1/2-in. maximum size aggregate (alternate mix)							
1	3	4	5	16.5	1500	22	2200

*Mix proportions will vary slightly depending on gradation of aggregates. A 10 per cent allowance for normal wastage has been included in the above figures for fine and coarse aggregate.

**One bag of cement equals 1 cu.ft.

21083

Example: How much material will be required to place a 4-in.-thick concrete floor in a building 24 x 14 ft.?

Computation: First find the number of cubic feet of concrete required by multiplying length of floor times the width of floor times the thickness in ft. (4 in. = 1/3 foot).

$$24 \times 14 \times 1/3 = \frac{112 \text{ cu.ft.}}{27} = 4.15 \text{ cu. yd.}$$

Table 11 shows that to produce 1 cu.yd. of concrete (1:2-1/4:3 mix) requires 6-1/4 bags of portland cement, 15.5 cu.ft. of fine aggregate, and 21 cu.ft. of coarse aggregate. Therefore, 4.15 cu.yd. will require 4.15 times these amounts:

4.15 X 6-1/4 = 26 bags of cement

4.15 X 15.5 = 64-1/3 cu.ft. fine aggregate = 2-1/2 cu.yd.

4.15 X 21 = 87-1/4 cu.ft. coarse aggregate = 3-1/4 cu.yd.

Table 13. Continuous Footing

Concrete footing size	Lin.ft. of footing		Factor*	
8 x 16-in.		X	3.5	=
10 x 20-in.		X	5.4	=
12 x 24-in.		X	7.7	=

*Includes adequate allowance for waste.

Total _____

Total divided by 100 = _____ cu.yd.

Example: An 8 x 16-in. footing for a 20 x 40-ft. building would require how many cubic yards of concrete?

Computation: 120 lin.ft. of footing multiplied by 3.5 (factor from table above) = 420 divided by 100 = 4.20. Use 4-1/4 cu.yd. concrete.

Table 14. Continuous Foundation

Foundation thickness, in.	Height, ft.		Length, ft.	Factor*	
6		X	X	2.0	=
8		X	X	2.6	=
10		X	X	3.2	=
12		X	X	3.8	=

*Includes adequate allowance for waste.

Total _____

Total divided by 100 = _____ cu.yd.

Example: An 8-in.-thick foundation 5 ft. high by 25 ft. long would require how much concrete?

Computation: 5 X 25 = 125
125 X 2.6 (8-in. thickness from table above)
= 325 divided by 100 = 3-1/4 cu.yd.

(or) $\frac{5 \times 25 \times 2.6}{100} = 3\text{-}1/4$ cu.yd.

21085

Table 15. Floor Slabs

Thickness of floor, in.	Area in sq.ft. length X width	Factor*	
4	X	1.3	=
5	X	1.6	=
6	X	2.0	=

*Includes adequate allowance for waste.

Total _____

Total divided by 100 = _____cu.yd.

Example: How much concrete is required for a 4-in.-thick slab 40 x 60 ft.?

Computation: 40 X 60 = 2,400 sq.ft. (area)
2,400 multiplied by 1.3 (factor from table above) = 3,120
3,120 divided by 100 = 31.2. Use 31-1/4 cu.yd.

USING A CONCRETE CALCULATOR

For quick calculations, small concrete calculators are often used. These small slide rules are not all accurately calibrated. At best, they can be only as accurate as the printing style and method used. However, they can be very useful for checking estimates and for quick estimating of small quantities of concrete.

APPLICATION

Discuss methods of estimating concrete for a job.
Reproduce, show, and discuss concrete estimating short-cut tables.
Demonstrate use of a concrete calculator.

TEST OR DISCUSSION POINTS

1. What is the unit of measure for estimating concrete requirements?
2. What is the formula for figuring concrete requirements?
3. Is the amount of concrete determined by the formula adequate for all jobs? Why?
4. For job batching, which materials need to be figured separately?
5. How many cubic yards of concrete would be required for the following?
   a. A grade beam 12 in. wide and 2 ft. deep for a 35x100-ft. building.
   b. A 6-in. floor slab for a 40x135-ft. building.
   c. A 4-in.-thick sidewall 3 ft. wide and 45 ft. long.
6. To the above solutions, what percentage should be added for waste and slight variations in thickness?
7. Can small concrete calculators be relied on for accurate estimates? Why?
8. Of what value are concrete calculators?

TOOLS AND MATERIALS

Reproduced tables for estimating concrete
Concrete calculator(s)

21087

TOOLS FOR PLACING AND FINISHING CONCRETE SLABS

It would take considerable time to discuss every tool that is now available for concrete work. Such a discussion is further complicated because new labor-saving tools are becoming available periodically. For these reasons, this information will deal only with those tools that are most commonly used for placing and finishing concrete.

STRAIGHTEDGE

A straightedge or strike-off rod (Fig. 36) is usually a specially prepared tool. It is the first finishing tool used after the concrete is placed and is used to strike off the concrete surface to proper grade.

A straightedge may be metal-clad or of lumber, as shown in Fig. 36, that has sufficient rigidity to perform the strike-off operation. The wood straightedge is generally made of 1-1/4-in. stock. In some sections of the country, workmen prefer to work with a shoe strip attached at the bottom (Fig. 37). A magnesium strike-off is usually 1 in. thick, 4-1/2 in. wide, and from 6 to 16 ft. in length.

Fig. 36. Straightedge or strikeoff rod.

Fig. 37. Straightedge with shoe strip.

It is best to use a tool that has been specifically made for striking off the concrete instead of just a piece of lumber. However, a straight piece of 2x4 or 2x6 may be used.

The striking surface of a straightedge should always be straight and true. The straightedge should be longer than the widest distance between the screeds or edge forms. It is good practice to consider 12 ft. as the maximum span to strike off by hand. With greater spans there is a tendency for a sag or rollback to develop. When this occurs power equipment should be used or screeds should be placed closer together.

P801S

21088

Fig. 38. Hand tamper, commonly called a jitterbug.

HAND TAMPER

After the concrete has been struck off, hand tampers (Fig. 38) can be used to compact the concrete in flatwork construction into a dense mass.

One common form of hand tamper is better known in the trade as a "jitterbug." Its base is usually made of a metal grill 6-1/2 in. wide by 36 in. or 48 in. long. Tampers are used to force the large particles of coarse aggregate slightly below the surface to enable the concrete finisher to put the desired finish on the surface. This tool should be used only with concrete having a very low slump--about 1 in.-- and should be used to bring just enough mortar to the surface for proper finishing. The jitterbug or tamper should be used sparingly and in most cases is not recommended and not necessary. The user can proceed directly to darbying or bullfloating, the next step in quality finishing.

DARBY

A darby (Fig. 39) is a long, flat, rectangular piece of wood, aluminum, or magnesium from 3 to 4 in. wide with a handle on top. It is used to float the surface of the concrete slab immediately after it has been struck off to prepare it for the next step in finishing. This tool should be used to eliminate any high or low spots or ridges left by the straightedge. It should also sufficiently embed the coarse aggregate for subsequent floating and troweling.

Fig. 39. Darby.

21089

BULL FLOAT

A bull float (Fig. 40) is a large flat, rectangular piece of wood, aluminum or magnesium, usually 8 in. wide and 42 to 60 in. long with a handle 4 to 16 ft. long. The function of the bull float is essentially the same as that of the darby, but it enables the concrete finisher to float a larger section of a wide slab. The bull float is more commonly used outdoors or where there is enough room to use the long handle.

Fig. 40. Bull float.

Fig. 41. Edger.

EDGER

Edgers (Fig. 41) come in many sizes; all are about 6 in. long and vary in width from 1-1/2 in. to 4 in. Lips range from 1/8 in. to 5/8 in., and radii from 1/8 in. to 1-1/2 in. The curved-end edger is one of the more popular types. Edgers are used to produce a radius at the edge of a slab. This improves the appearance and reduces the risk of damage to the edge.

JOINTER OR GROOVER

Jointers (Fig. 42), sometimes called groovers, are about 6 in. long and vary from 2 to 4-1/2 in. wide. They have shallow, medium, or deep bits (cutting edges) running from 3/16- to 1-in. in depth. The jointer is used to cut a joint partly through fresh concrete. It may be for appearance or can act as a control joint if cut 1/4 to 1/5 the depth of the slab. The control joints (sometimes also referred to as dummy or contraction joints) are used to predetermine the location of any possible cracks.

Fig. 42. Jointer or groover.

21090

Fig. 43. Power joint cutter.

POWER JOINT CUTTER

Another method of cutting joints in concrete slabs is with an electric or gasoline-driven saw (Fig. 43) fitted with a shatterproof abrasive or diamond blade. A power cutter produces a narrow joint that minimizes the possibilities of spalling at the joint due to traffic. The joint is generally cut in the concrete surface 4 to 12 hours after the concrete has hardened, or as soon as the concrete surface will not be damaged by the saw kerfs.

HAND AND POWER FLOATS

Hand floats are made of aluminum, magnesium, or wood. Aluminum or magnesium floats (Fig. 44) are usually made in two sizes, 12 or 16 in. long by 3-1/2 in. wide. Wood floats (Fig. 45) are 12, 15, or 18 in. long and 3-1/2 or 4-1/2 in. wide.

Fig. 44. Lightweight metal float.

The hand float is used to prepare the concrete surface for troweling. Hand floats are also used for floating the concrete around pipes and columns, against walls or other areas which power floats cannot reach.

Fig. 45. Wood float.

After the concrete is stiff enough to support the weight of a man, a power float can be used to compact the concrete. These floating machines perform the same operations as hand floating but cover larger areas faster.

Power floats are driven by electric motors or gasoline engines. A power float with a rotating disk about 2 ft. in diameter (Fig. 46) is used only with no-slump concrete for

Fig. 46. Power float.

21091

heavy duty floor construction. For slab construction a power trowel (Fig. 48) with clip-on or shoe-type float blades is usually used.

Fig. 47. Steel hand trowel.

HAND AND POWER TROWELS

The steel hand trowel comes in many different sizes ranging from 10 to 20 in. long and 3 to 4-3/4 in. wide (Fig. 47).

Each size trowel has its own use. For the first troweling of concrete flatwork, a wide trowel 16 to 20 in. long is generally used. For troweling the slab the last few times, most finishers prefer a "fanning" trowel 14 to 16 in. long and 3 to 4 in. wide.

A power trowel has three or four rotating steel trowel blades (Fig. 48). They are powered by electricity or by gasoline engine.

The purpose of steel troweling is to give the surface a dense, smooth finish.

Fig. 48. Power trowel.

21092

APPLICATION

Discuss finishing tools used for flat work.

TEST OR DISCUSSION POINTS

1. Name some of the tools commonly used for finishing concrete.
2. Is it necessary that a straightedge be made of wood? Why?
3. When should a jitterbug be used?
4. When is a bull float used?
5. Why are jointers used?
6. At what time should a power cutter be used for cutting joints?
7. What are some of the materials used to make floats?
8. Explain the advantages of power floats or trowels.

TOOLS AND MATERIALS

Placing and finishing tools (If these are not available perhaps they can be borrowed from a contractor for classroom use.)

21093

SELECTION AND DESIGN OF CONCRETE MIXTURES

The design of concrete mixtures is the determination of the most economical and practical combination of concrete ingredients that is workable in its plastic state and that will develop the required qualities when hardened. Thus, a properly designed concrete mix achieves three objectives:

1. Required qualities of hardened concrete.
2. Workability of fresh concrete.
3. Economy.

If acceptable materials are used, the qualities of hardened concrete such as resistance to freezing and thawing, watertightness, wear resistance, and strength are dependent upon (1) water-cement ratio, (2) entrained air, and (3) curing.

When possible, the method and length of curing should be anticipated in order to select the proper water-cement ratio. The air content desired in the concrete is dependent upon the amount of mortar in the mix; the amount of mortar, in turn, is usually dependent upon the maximum size of coarse aggregate.

Workability of fresh concrete is the property that determines the amount of work required to fully consolidate the concrete. Although workability is difficult to measure, it can be readily judged by experienced technicians. Thus, the design of a concrete mix is an art as well as a science.

To achieve economy, the aim of concrete mix design should be to minimize the amount of cement required without sacrificing concrete quality. Since quality is primarily dependent upon water-cement ratio, the water requirement should be minimized to reduce the cement requirement. Steps to minimize water and cement requirements include use of (1) the stiffest practicable mixture, (2) the largest practicable size aggregate, and (3) the optimum ratio of fine to coarse aggregates. As will be shown later, the relative costs of fine and coarse aggregates should also be considered in determining the most economical mix proportions.

SELECTING MIX CHARACTERISTICS

Before a concrete mixture can be designed, certain criteria must be known. The size, shape, and required concrete strength of the structure and its exposure conditions must be ascertained. Since most of the desired properties of hardened concrete are dependent upon the quality of the cement paste, the first step in the design of a concrete mix is the selection of the appropriate water-cement ratio.

2085

used for various exposure conditions. Note that the quantities shown are the maximum permissible water-cement ratios.

Under certain conditions, as indicated in Table 2, the water-cement ratio should be selected on a basis of concrete strength. In such cases, if at all possible, tests should be made with the job materials to determine the relationship between water-cement ratio and strength. If data for this relationship cannot be obtained because of time limitations, the water-cement ratio may be estimated from Fig. 17. A large majority of the results of strength tests made by many laboratories using a variety of materials falls within the band curves.

Table 2. Maximum Permissible Water-Cement Ratios (Gal. per Bag) for Different Types of Structures and Degrees of Exposure*

Type of structures	Exposure conditions**					
	Severe wide range in temperature, or frequent alterations of freezing and thawing (air-entrained concrete only)			Mild temperature rarely below freezing, or rainy, or arid		
	In air	At the water line or within the range of fluctuating water level or spray		In air	At the water line or within the range of fluctuating water level or spray	
		In fresh water	In sea water or in contact with sulfates †		In fresh water	In sea water or in contact with sulfates †
A. Thin sections such as reinforced piles and pipe	5.5	5.0	4.5	6	5.5	4.5
B. Thin sections such as railings, curbs, sills, ledges, ornamental or architectural concrete, and all sections with less than 1-in. concrete cover over reinforcement	5.5	–	–	6	5.5	–
C. Moderate sections, such as retaining walls, abutments, piers, girders, beams	6.0	5.5	5.0	††	6.0	5.0

***Air-entrained concrete should be used under all conditions involving severe exposure and may be used under mild exposure conditions to improve workability of the mixture.*
†Soil or ground water containing sulfate concentrations of more than 0.2 per cent. For moderate sulfate resistance, the tricalcium aluminate content of the cement should be limited to 8 per cent, and for high sulfate resistance to 5 per cent.
††Water-cement ratio should be selected on basis of strength and workability requirements, but should not exceed 9 gal. per bag.

21095

Fig. 17. Relationship between water-cement ratio and compressive strength for Types I and III portland cements at different ages. These relationships are approximate and should be used only as a guide in lieu of data on job materials.

If the design is based on flexural rather than compressive strength, tests should be made to determine the relationship between water-cement ratio and flexural strength. An approximate relationship between flexural and compressive strength is:

$$f'_c = \left(\frac{R}{K}\right)^2$$

in which f'_c = compressive strength in psi;
R = flexural strength (modulus of rupture) in psi; and
K = a constant, usually between 8 and 10.

If the exposure conditions and the strength must both be considered, the lower of the two indicated water-cement ratios should be used.

Maximum Aggregate Size

The maximum size of coarse aggregate that can be used depends on the

size and shape of the concrete members and the amount and distribution of reinforcing steel. Generally, the maximum size should not exceed one-fifth the minimum dimension of the member, nor three-fourths the clear space between reinforcing bars or between reinforcement and the forms. For unreinforced slabs on ground, the maximum size should not exceed one-third the slab thickness. Smaller sizes may be used when indicated by availability and considerations of economy.

The amount of mixing water required to produce a cubic yard of concrete of a given slump (a measure of fluidity) is dependent on the maximum size of aggregate--the smaller the maximum size of aggregate, the greater the amount of water required. It is therefore advisable to use the largest practicable maximum size of coarse aggregate. This minimizes the water requirement, and hence the cement content is kept to a minimum.

The maximum size of coarse aggregate that produces concrete of maximum strength for a given cement content depends upon aggregate source and the aggregate shape and grading. For many aggregates, this "optimum" maximum size is about 3/4 in. If strength is the primary consideration in the design of a concrete mix, use of the maximum size of aggregate that is optimum for strength is suggested.

Air Content

Entrained air should be used in all concrete exposed to freezing and thawing and may be used for mild exposure conditions to improve workability. The recommended total air contents for air-entrained concretes are shown in Table 3. Note that the amount of air required to provide adequate freeze-thaw resistance is dependent upon the maximum size of aggregate. Entrained air is contained in the mortar fraction of the concrete, and in properly designed mixes, the mortar content decreases as the maximum aggregate size increases.

Fig. 17 shows a lower compressive strength for similar water-cement ratios when air is entrained. Air-entrained concretes require less mixing water, however, to maintain equal slumps, as indicated in Table 3. When the cement content is maintained, the water-cement ratio is lowered. Hence, the strength of air-entrained concrete is generally only slightly less than that of non-air-entrained concrete.

Slump

The slump test is generally used as a measure of the fluidity of the concrete. It should not be used to compare mixes of wholly different proportions or mixes of different kinds or sizes of aggregates. Under conditions of uniform operation, changes in slump indicate changes in materials, mix proportions, or water content. To avoid mixes too stiff or too fluid, slumps within the limits given in Table 4 are suggested.

21097

***These quantities of mixing water are for use in computing cement factors for trial batches. They are maxima for reasonably well-shaped angular coarse aggregates graded within limits of accepted specifications.*
† Plus or minus 1 per cent.

TRIAL MIX METHOD

The most direct method for determining optimum mix proportions is through the use of trial mixes. Such mixes may be (1) relatively small batches made with laboratory precision or (2) job-size batches made during the course of normal concrete production. Use of a combination of both methods is often most satisfactory. In either method, the items listed previously (water-cement ratio, maximum size of aggregate, air content, and range of slump) must be selected first. By maintaining each of these items constant while varying the amounts of fine and coarse aggregates, a series of mixes is made. Proportions are computed for each mix and results are compared. Based on considerations of workability and economy, the mix proportions are selected.

Table 4. Typical Slump Ranges for Various Types of Construction

Types of construction	Slump, in.*	
	Maximum	Minimum
Reinforced foundation walls and footings	4	2
Unreinforced footings, caissons, and substructure walls	3	1
Reinforced slabs, beams, and walls	5	2
Building columns	5	3
Pavements	2	1
Sidewalks, driveways, and slabs on ground	4	2
Heavy mass construction	2	1

**When high-frequency vibrators are not used, the values may be increased by about 50 per cent, but in no case should the slump exceed 6 in.*

21099

Laboratory Trial Mixes

EXAMPLE. To illustrate the procedure, assume that the mix proportions are to to be determined for the following:

Conditions. Concrete is required for a retaining wall that will be exposed to fresh water in a severe climate. A design compressive strength of 3,000 psi at 28 days is specified. Minimum thickness of the wall is 8 in., and 2 in. of concrete cover over the reinforcement is required.

Water-cement ratio. For these exposure conditions, line C of Table 2 indicates that air-entrained concrete with a maximum water-cement ratio of 5.5 gal. per bag should be used. Water-cement ratio required for strength from Fig. 17 should be between 5.8 and 6.8 gal. per bag (see dashed lines in graph for 28-day strength of Type I cement), assuming that the mix is designed for 3,450 psi (3,000 + 15 per cent*) to allow for job variations. These water-cement ratios are greater than that permitted for exposure conditions. Because of the exposure requirements, not more than 5.5 gal. per bag should be used, even though this water-cement ratio will produce strengths higher than needed for structural purposes.

Aggregate size. From the information given, the maximum size of aggregates should not exceed 1-1/2 in. Assume that satisfactory 1-1/2 in. maximum size aggregate is economically available and will be used. If this size were not available, the next smaller available size would be used.

Air content. Because of the severe exposure conditions, concrete should contain entrained air. From Table 3, the recommended air content for concrete with 1-1/2 in. aggregate is 5 per cent plus or minus 1 per cent.

To entrain air, either an air-entraining portland cement or an air-entraining admixture must be used. Unless an air-entraining cement is used, sufficient air-entraining admixture must be added to a portion of the mixing water to assure the desired air content. The amount recommended by the manufacturer will, in most cases, produce the desired air content.

Slump. A typical slump range for a reinforced foundation wall is 2 to 4 in., assuming that the concrete will be consolidated by vibration (Table 4).

All trial mix data are entered in the appropriate blanks on the trial mix data sheet, Fig. 18.

Representative samples of the aggregates, cement, water and air-entraining admixture must be used. To simplify calculations and to eliminate sources of error caused by variations in aggregate moisture content, the aggregates should be pre-wetted and allowed to dry to a saturated, surface-dry condition. They should then be placed in covered containers to keep them in this condition until use.

The size of the trial batch is dependent on the equipment available, and on the number and size of test specimens to be made. If the batches are to be mixed

**See ACI Standard Recommended Practice for Evaluation of Compression Test Results of Field Concrete (ACI 214-57).*

1 Canadian bag of cement = 87-1/2 lb.

Fig. 18. Data sheet for laboratory trial mixes, page 2.

by hand and if no compression test specimens are required, a 0.1-bag batch may be adequate; however, larger batches will produce more accurate data. Machine mixing is recommended since it more nearly represents job conditions; it is mandatory if the concrete is to contain entrained air.

Batch weights. For convenience, a batch containing 0.2 bag of cement will be made. The quantity of mixing water required is therefore 0.2 × 5.5 gal. = 1.1 gal., or 9.2 lb. These quantities of cement and water are carefully weighed. Representative samples of fine and coarse aggregates in suitable containers are weighed. These weights are indicated as initial weights in column 2 of the data sheet (Fig. 18).

All of the measured quantities of cement, water, and air-entraining admixture are to be used. Fine and coarse aggregates are added to produce a workable concrete mixture having a slump adequate for placement in a retaining wall. An experienced technician can determine if the slump is adequate by noting

21161

if the ingredients tend to segregate; he can also observe if the concrete is workable. By adding fine and coarse aggregates in small increments, he controls the slump.

Excessive coarse aggregate will produce a harsh unworkable mix; excessive fine aggregate will result in an uneconomical mix with high water and cement requirements and greater potential volume changes. A rule of thumb is to use as much coarse aggregate as possible with sufficient fine aggregate to ensure adequate workability. Mechanical mixing, simulating the type to be used on the project, should be used to obtain the most reliable results.

Workability. When the slump of the concrete appears to be within the recommended range, tests for slump, air content, and unit weight are made. Results of these tests are noted on the data sheet as well as a description of the workability, which is noted as "Excellent" for the example. Weights of fine and coarse aggregates not used are recorded on the data sheet (Fig.18) in column 3, and the weights of materials used are noted in column 4 (column 2 minus column 3). Since the batch was based on a 0.2-bag mix, the quantities for a 1-bag mix are equal to the weights used multiplied by 5.

If the slump had been greater than that required, small quantities of fine or coarse aggregate (or both) would be added. Had the slump been less than required, water and cement, in the appropriate ratio, would be added to produce the desired slump. With the latter procedure, it would be important that the quantities be measured accurately and recorded on the data sheet.

Table 5. Example of Results of Laboratory Trial Mixes

Batch No.	Slump, in.	Air content, per cent	Unit wt., pcf	Cement factor, bags/ cu.yd.	Fine aggregate, per cent of total aggregate	Work-ability
1	3	5.4	144	5.75	33.5	Excellent
2	2¾	4.9	144	5.90	27.4	Harsh
3	2½	5.1	144	5.92	36.1	Excellent
4	3¼	4.7	145	5.75	30.5	Good

Fig. 19. Example of relationship between percentage of fine aggregate and cement content for a given water-cement ratio and slump.

Finding the yield and cement factor. The yield, as defined by the American Society for Testing and Materials, is the volume of concrete produced from a 1-bag mixture. It is equal to the weight of a 1-bag batch divided by the unit weight of the concrete. The number of bags of cement required per cubic yard of con-

21102

crete (cement factor) is computed by dividing 27 (cubic feet per cubic yard) by the yield in cubic feet. The percentage of fine aggregate of total aggregate is also calculated. In this trial batch the cement factor was 5.75 bags per cubic yard, the unit weight of the concrete was 144 pcf, and the fine aggregate made up 33.5 per cent of the total aggregate by weight.

To determine the most economical proportions, additional trial batches should be made varying the percentage of fine aggregate. In each batch the water-cement ratio, aggregate gradations, air content, and slump are maintained approximately the same. Results of four such trial batches are summarized in Table 5.

Quantities. For these mixes, the percentage of fine aggregate is plotted against the cement factor in Fig. 19. Note that for the combination of materials used, the minimum cement factor (5.74 bags per cubic yard) occurs at a fine aggregate content of about 32 percent of total aggregate. Since the water-cement ratio is 5.5 gal. per bag, and the unit weight of the concrete for an air content of 5 percent is about 144 pcf, the quantities of materials required per cubic yard can be computed:

Cement	5.74 bags	= 539 lb.
Water	5.74 × 5.5 × 8.33	= 262 lb.
Cement + water		= 801 lb.
Wt. concrete per cu.yd.	= 144 × 27	= 3,888 lb.
Wt. aggregates	= 3,888 − 801	= 3,087 lb.
Wt. fine aggregate	$= \frac{32}{100} \times 3{,}087$	= 990 lb.
Wt. coarse aggregate	= 3,087 − 990	= 2,097 lb.

Unless care is taken to control the slump and air content, and unless weights are accurately determined, it may be difficult to obtain data necessary to plot a curve such as Fig. 19. For well-graded, rounded aggregates the curve may be nearly flat. If there is a wide difference in the costs of fine and coarse aggregates, the optimum per cent of fine aggregate for economy may be different than that at which the minimum cement factor occurs. For example, if coarse aggregate costs more than fine aggregate, it may be more economical to use more fine aggregate, with an appropriate increase in cement content.

Job-Size Trial Batches

On most jobs, trial batches may be full size. These batches are often used in the foundations during the early phases of a construction project. The first trial may be selected on the basis of experience or from established relationships such as those given in Tables 6 and 7. These tables have been developed from experience and data from several sources. They indicate the amount of water required per cubic yard of concrete, cement content, and the porportion of fine aggregate required for good workability.

The quantities in Tables 6 and 7 are based on concrete having a slump of 3 to 4 in., with well-graded aggregates having a specific gravity of 2.65. The dry-rodded unit weight of the coarse aggregate was assumed to vary from 98 to 106 lb.

21103

per cubic foot for maximum sizes of 3/8 in. to 1-1/2 in., respectively. For other conditions it is necessary to recalculate the quantities in accordance with the footnotes. When making a trial batch, enough water should be added to produce the desired slump, whether this is more or less than the estimated amount. Slump, air content, and unit weight of the fresh concrete should then be measured.

EXAMPLE. To illustrate this method, assume that the mix proportions are to be determined for the following:

Conditions. A water-cement ratio of 6 gal. per bag, maximum aggregate size of 1 in., air content 6 ± 1 per cent, and a slump of 2 to 4 in. The fine aggregate has a fineness modulus of 2.85 and a moisture content of 4.3 per cent. The coarse aggregate has a moisture content of 1 per cent.

Weight. For these conditions, Table 6 shows the following quantities per cubic yard of concrete:

Cement	5.7 bags	=	536 lb.
Water	34 gal.	=	283 lb.
Fine aggregate		=	1,165 lb.
Coarse aggregate		=	1,835 lb.
	Total	=	3,819 lb.

The free moisture (above saturated, surface-dry) in the fine aggregate amounts to 4.3 per cent of 1,165 lb., or 50 lb.; the free moisture in the coarse aggregate is approximately 18 lb. The corrected weights per cubic yard of concrete are:

Cement (Type IA)	536 + 0	=	536 lb.
Water	283 - 50 - 18	=	215 lb.
Fine aggregate	1,165 + 50	=	1,215 lb.
Coarse aggregate	1,835 + 18	=	1,853 lb.
	Total	=	3,819 lb.

When these quantities of materials were mixed, the consistency was such that the slump was less than 1 in. Additional water (3 gal.) was added to bring the slump to 3 in. The air content was measured to be 5.3 per cent and the unit weight was measured to be 144 pcf. The workability of the mix was noted as good. The total amount of water used was 308 lb. (283 + 25), and total weight of concrete produced was 3,844 lb. (3,819 + 25).

Volume. Since the unit weight of the concrete was 144 pcf, the volume of concrete in this batch was 26.7 cu.ft. (3,844 lb. ÷ 144 pcf).

The principal reason for the discrepancy between actual and theoretical yield is that the specific gravity values of the aggregates were probably different from those assumed in Tables 6 and 7. Therefore these quantities must be adjusted to produce 27 cu.ft. of concrete and to maintain the water-cement ratio at 6 gal. per bag. Unless the corrections are very large, certain simplified assumptions can be made. These are that the unit weight of the concrete remains essentially constant and that the amount of water required (per cubic yard of concrete) remains constant.

Adjustment. The adjusted water requirement is thus:

$$\frac{27}{26.7} \times 308 = 312 \text{ lb.} = 37.4 \text{ gal.}$$

and the cement requirement is $\frac{37.4}{6} = 6.23$ bags or 586 lb.

The weight of materials per cubic yard of concrete must total 144 × 27 = 3,888 lb. The total weight of aggregates must therefore be

**Increase or decrease water per cubic yard by 3 per cent for each increase or decrease of 1 in. in slump. For manufactured fine aggregate, increase percentage of fine aggregate by 3 and water by 2 gal. per cubic yard of concrete. For less workable concrete, as in pavements, decrease percentage of fine aggregate by 3 and water by 1 gal. per cubic yard of concrete.*

***For definition of fineness modulus, see Aggregates for Concrete, available only in the United States and Canada on request from the Portland Cement Association.*

21105

3,888 - (312 + 586) = 2,990 lb. For this ratio of fine to coarse aggregates, saturated, surface-dry weights are thus 1,160 lb. and 1,830 lb., respectively.

To determine the optimum proportions for economy of materials, additional trial batches should be made varying the ratio of fine and coarse aggregates, as discussed under "Laboratory Trial Mixes."

APPLICATION

Discuss the unit weight method of selection and design of a concrete mixture. (If equipment and materials are available, run through an actual mix design example.)
Show film, Principles of Quality Concrete (See film list)

TEST OR DISCUSSION POINTS

1. What is the design of a concrete mixture?
2. What are the three objectives of a properly designed concrete mixture?
3. Explain what "economy" refers to in mix design.
4. Name the three most direct trial mix methods for determining optimum mix proportions.
5. Explain what you feel would be the best size for a trial batch.
6. How can air be entrained in a trial batch?
7. Excessive coarse aggregate will produce what type of mix?
8. Excessive fine aggregate will produce what type of mix?
9. Explain two methods for selecting trial batches.
10. How would you determine optimum proportions for economy of materials?

TOOLS AND MATERIALS

Reproduce trial mix data sheet and tables from Related Information for this unit.

QUALITY READY MIXED CONCRETE

Most concrete used in construction is mixed and delivered to the job site. Exceptions involve massive structures on the one extreme--dams, for example, where it is economical to provide a concrete plant exclusively for the one job--and very small projects on the other extreme, where less than one full load of ready mixed concrete may be needed.

PRODUCTION OF READY MIXED CONCRETE

Using precision scales to weigh ingredients, ready mix plants batch portland cement with aggregates and water to achieve the desired concrete mixture.

The producer is responsible for selecting and proportioning the ingredients as specified by the purchaser and delivering the concrete in good condition. From the time of delivery, the quality of the hardened concrete depends entirely on the user, who assumes responsibility for placing, finishing, and curing. Obtaining concrete construction of high quality is a joint responsibility of the producer and user.

21108

Ready mixed concrete is manufactured for delivery to the job site in a plastic and unhardened state. Any of three types of mixing can be used:

1. Transit-mixed concrete is mixed completely in a truck mixer.

2. Central-mixed concrete is mixed completely in a stationary mixer and is delivered in a truck agitator, a truck mixer operating at agitating speed, or a special non-agitating truck.

3. Shrink-mixed concrete is mixed partially in a stationary mixer and the mixing is completed in a truck mixer.

The "Standard Specifications for Ready-Mixed Concrete" (ASTM C94) requires that mixers and agitators be operated within the limits and speed of rotation designated by the equipment manufacturer. Agitating speed is usually about 2 to 6 rpm, while mixing speed is generally about 8 to 12 rpm. Truck mixers consist essentially of a mixer with a separate water tank and water measuring device mounted on a chassis. Agitator trucks are similar but without provision for water.

ASTM C94 requires that when a truck mixer is used either for complete mixing or to complete the partial mixing, each batch of concrete should be mixed not less than 50 nor more than 100 revolutions of the drum or blades at the rate of rotation designated by the manufacturer as mixing speed. Any additional mixing should be done at the speed designated by the manufacturer as agitation speed. The specifications also require that concrete be delivered and discharged within 1-1/2 hours or before the drum has revolved 300 times after introduction of the water to the cement and aggregates or the cement to the aggregates.

ADVANTAGES OF READY MIXED CONCRETE

A look at some of the practical benefits offered by ready mixed concrete will explain the phenomenal growth of this industry in recent years.

Today, the use of modern precision batching equipment in the ready mix industry assures purchasers of an accurately proportioned mix. Thorough mixing of each batch helps produce a concrete of uniform quality, durability, and high strength.

Use of ready mixed concrete helps create a more efficient operation at the job site. It eliminates time spent in estimating quantities of cement and aggregates to use and labor required to handle and mix materials. The problem of finding space at the job site for stocking aggregates and storing cement is eliminated. Excess materials aren't left to clean up after a job is completed. Specialized equipment and personnel for job-mixing, which may be used inefficiently because of fluctuating demand for concrete, are eliminated.

21109

Virtually any location is accessible to a ready mix truck. This mobility makes it possible to deliver concrete to a specific job site at the time required, ready for depositing in the forms. Construction crews don't have to lose time waiting to start or finish a job.

Efficient, large-volume production makes ready mixed concrete an economical material to use in modern construction. It is delivered in the exact quantity desired, eliminating waste and costly reordering. A mixer doesn't have to be rented, leased, or purchased for use on the job. There isn't any guesswork about the cost of the concrete either. Ready mix producers will quote the price of their product before making delivery.

SPECIFICATIONS FOR READY MIXED CONCRETE

Many engineers and architects now designate standard specifications for ready mixed concrete. Commonly used is the "Standard Specifications for Ready Mixed Concrete," (ASTM Designation C94). This is the standard of the American Society for Testing and Materials.

The specification covers the producer's responsibility for ready mixed concrete through delivery to the job site. Among the subjects covered are: basis of purchase, materials, quality of concrete, tolerances in slump, measuring materials, etc. However, they do not cover the placement, consolidation, curing, or protection of the concrete after delivery to the purchaser. These are the user's responsibilities.

In the absence of designated applicable general specifications, the purchaser must select one of two following alternative bases for specifying the quality of the concrete:

Alternate No. 1 is used when the purchaser assumes responsibility for the design of the concrete mixture. He must specify the following:

(1) Cement content in bags per cubic yard of concrete, or equivalent units.

(2) Designated size, or sizes, of coarse aggregate.

(3) Maximum allowable water content in gallons per bag of cement or equivalent units, including surface moisture, but excluding water of absorption, of the aggregates.

(4) Slump, or slumps, desired at the point of delivery.

(5) When air-entraining concrete is specified, the maximum and minimum limits for air content of samples taken from the transportation unit at the point of discharge.

21110

Alternate No. 2 is used when the purchaser requires the manufacturer to assume responsibility for the design of the concrete mixture. It is the same as alternate No. 1 with the exception of item (1) which reads: "Minimum allowable compressive strength as determined on samples taken from the transportation unit at the point of discharge. The basis shall be the compressive strength at 28 days. The purchaser shall specify the requirements for strength in terms of tests of standard specimens cured under standard laboratory conditions for moist curing."

After reading ASTM C94, one can understand why the purchaser designating this standard specification when ordering should receive a quality product.

REMIXING CONCRETE

The initial set of concrete does not ordinarily take place for 2 or 3 hours after the cement has been mixed with water. Fresh concrete that is left standing tends to dry out and stiffen somewhat before it begins to set. Such concrete may be used, if upon remixing it becomes sufficiently plastic that it can be completely compacted in the forms. Indiscriminate addition of water to make the mixture more workable should not be allowed since this lowers the quality just as would a larger amount of water in the original mixing. Under careful supervision, a small increment of water may be added to delayed batches provided that the maximum allowable water-cement ratio is not exceeded and provided that the concrete is remixed for at least half the minimum required mixing time.

PREPARING FOR READY MIX DELIVERY

Order ready mixed concrete well in advance for speedy and efficient service. Specify the hour when the concrete is needed. Doing this permits delivery schedules to be adapted to your work schedule. When you place an order, the ready mix producer will tell you approximately when your concrete will be delivered.

Plan placing operations far enough in advance of an order so that trucks can be scheduled to deliver concrete at the time it is needed. If the job is not ready for placing to begin when trucks arrive, excessive mixing and hydration may cause the concrete to become too stiff to place and finish.

Ready mixed concrete must be placed in the forms promptly--not more than about 1-1/2 hours after mixing. The time may be reduced during extremely hot weather. Have adequate facilities and labor available to handle the concrete when delivered.

Delays are costly in terms of lost time and quality. They may even result in the loss of the concrete. Expensive equipment may be tied up, affecting the cost per cubic yard. You may have to absorb this added expense.

Advance planning and preparation will save time and reduce confusion on the job. Here are some things you can do:

Fig. 24. Have forms well braced to keep them aligned while concrete is being placed. Oil forms so they can be removed easily.

Fig. 25. Have wheelbarrows handy to speed placing of concrete immediately upon delivery at the work site.

Fig. 26. Have subgrade dampened so the ground doesn't absorb water from the concrete, and level to ensure uniform concrete thickness.

Fig. 27. Have strike-off boards ready and screeds in place to make sure that concrete will be finished to proper grade.

21112

Fig. 28. Have planks and runways in place to protect existing construction and provide easy access for trucks.

Fig. 29. Have vibration equipment ready to ensure proper compaction and bond to reinforcement and to help eliminate air pockets.

Fig. 30. Have straightedge ready to strike off concrete to the desired surface level before beginning finishing operations.

Fig. 31. Have curing materials ready to prevent rapid evaporation of surface water as a first step in proper curing.

21113

DANGERS OF ADDING WATER TO READY MIX

When the specified mix is ordered, the proper amount of water is determined at the plant and combined with the portland cement and aggregate. Addition of extra water to ready mixed concrete, which has been accurately designed for an individual job, will seriously affect the strength, durability, and watertightness of the finished concrete.

Many producers discourage the use of high slump concrete by requiring that requests for extra water at the job site be noted on the delivery ticket and signed by the user to acknowledge the addition of extra water. Drivers are usually trained not to add water indiscriminately at anyone's slightest wish. There is nothing wrong with delivering concrete to the job "on the dry side" and then adding water to bring the slump to the specified amount. When this procedure is used, an adequate amount of mixing must be performed to incorporate the added water into the mix.

Many fail to realize that too much water in a mix also results in additional man hours required for finishing. Finishers have to wait for the water to soak into the subgrade or evaporate. Stiff concrete usually is less expensive in terms of man hours required. The initial placing labor may be more than for a soupy mix, but the concrete can be finished sooner.

AVAILABILITY OF READY MIX

Ready mixed concrete is available for all types of construction. The mobility of mixer trucks makes most job sites easily accessible for the delivery of ready mixed concrete. After delivery, if quality concrete is combined with good workmanship, the completed job will give years of dependable service.

APPLICATION

Discuss quality ready mixed concrete.
Arrange tour of local ready mix plant.
Show film, Quality Ready Mixed Concrete (see film list).

TEST OR DISCUSSION POINTS

1. Identify and explain the three methods by which ready mixed concrete is mixed and delivered.
2. What are the producer's responsibilities with regard to the five construction rules of quality concrete?
3. What are the three responsibilities of the purchaser or user?
4. Explain some of the advantages of using ready mixed concrete.
5. Explain why advance planning and preparation are worth while.
6. What advance plans should the user make?
7. Why is it never advisable to add water to ready mixed concrete at the job?
8. Will excess water affect finishing time? If so, how?
9. What can architects, engineers, and others use as a standard specification for ready mixed concrete?
10. Explain the five items that must be stated explicitly in a specification for ready mixed concrete.

JOB MIXING CONCRETE

As discussed previously, the purchaser of concrete specifies the mix desired when ordering ready mixed concrete and is responsible for the concrete after it has been delivered to the job. However, in the case of job-mixed concrete, the user is responsible for selecting good ingredients and using the proper mix.

The selection of a proper mix is based on the kind of work or exposure condition the concrete will be subjected to.

The design of concrete mixtures is the determination of the most economical and practical combination of ingredients to make concrete workable in its plastic state and to make it develop required qualities when hardened. Commercial laboratories perform this service for many ready mix plants as well as for specific projects. However, for small concrete jobs this service is not always economical or practical, and someone must determine the mix on the job.

Quality concrete gives maximum service and satisfaction. It will result in installations that are durable, strong, and watertight. It is just as easy to make high-quality concrete that gives excellent service as to make poor quality concrete.

OBJECTIVES OF A CONCRETE MIX

A properly designed concrete mix achieves three objectives: (1) workability of fresh concrete, (2) required qualities of hardened concrete, and (3) economy.

Workability of fresh concrete is the property that determines the amount of effort required to consolidate and finish the concrete. Although workability is difficult to measure, it can be readily judged by experienced technicians. Thus, the design of a concrete mix is an art as well as a science.

Assuming that acceptable materials are used, the qualities of hardened concrete, such as resistance to freezing and thawing, watertightness, wear resistance, and strength, basically depend on the water-cement ratio.

To achieve economy, a concrete mix design should provide the maximum yield without sacrificing concrete quality. Since quality primarily depends on the water-cement ratio, the water requirement should be minimized to reduce the cement requirement. Steps to minimize water and cement requirements include use of (1) the stiffest practical mixture, (2) the largest size aggregate practical for the job, and (3) the optimum ratio of fine to coarse aggregate.

DETERMINING EXPOSURE CONDITIONS

The kind of work and exposure conditions that concrete will be subjected to

21116

should be known before a mixture is designed. Exposure conditions fall into three distinct classifications:

1. Mild exposure--conditions where concrete is not subjected to abrasion or severe weather (foundations and installations in mild climates where temperatures rarely fall below freezing).

2. Normal exposure--conditions where concrete is used for watertight structures and subjected to abrasion or weather (floors, sidewalks, paved barnyards, tilt-up wall panels, tanks).

3. Severe exposure--conditions where concrete is subjected to severe wear, weather, weak acids or alkali solutions (silos, mangers, floors in dairy plants).

WATER-CEMENT RATIOS FOR EXPOSURE CONDITIONS

When mixing concrete on the job, consider how the concrete will be used. A proper mix should be based on the kind of work or exposure conditions to which the concrete will be subjected. As previously discussed, desirable properties of quality concrete depend on the quality of the water-cement paste. To ensure quality concrete, the following desirable water-cement ratios have been established in terms of maximum water and minimum cement for the three exposure conditions:

FOR MILD EXPOSURES--7 gal. of water per bag of cement and 5 bags of cement per cubic yard of concrete.

Concrete not subject to abrasion or severe weather (foundations and installations in mild climates).

FOR NORMAL EXPOSURES--6 gal. of water per bag of cement and 6 bags of cement per cubic yard of concrete (air entrained).

Concrete for watertight structures and when subject to abrasion, weather (floors, sidewalks, paved barnyards, tilt-up wall panels, tanks).

FOR SEVERE EXPOSURES--5 gal. of water per bag of cement and 7 bags of cement per cubic yard of concrete (air entrained).

Concrete subjected to severe wear, weather, weak acids, or alkali solutions (silos, mangers, floors in dairy plants).

By using more or less aggregates (fine or coarse) the consistency of the mix can be varied. This helps make it more workable for a specific job.

21117

PROPER CONSISTENCY OF SLUMP

Under conditions of uniform operation, changes in slump indicate changes in materials, mix proportions, or water content. To avoid mixes that are too stiff or too fluid, slumps within the limits given in Table 8 are suggested. Concrete with a slump greater than 6 in. should not be used.

Table 8. Typical Slump Ranges For Various Types of Construction

Types of Construction	Slump, In.*	
	Maximum	Minimum
Reinforced foundation walls and footings	4	2
Unreinforced footings, caissons, and substructure walls	3	1
Reinforced slabs, beams, and walls	5	2
Building columns	5	3
Pavements	2	1
Sidewalks, driveways, and slabs on ground	4	2
Heavy mass construction	2	1

*When high-frequency vibrators are not used, the values may be increased by about 50 per cent, but in no case should the slump exceed 6 in.

WATER-CEMENT RATIO BASED ON REQUIRED COMPRESSIVE STRENGTH

Under certain conditions, the water-cement ratio should be selected on a basis of concrete strength. In such cases, if at all possible, tests should be made with the job materials to determine the relationship between water-cement ratio and strength. If data for this relationship cannot be obtained because of time limitations, the water-cement ratio may be estimated from Fig. 32. A large majority of the results of strength tests made by many laboratories using a variety of materials falls within the strength-band curves.

21118

*Concrete with air content within recommended limits and maximum aggregate size of 2 in. or less.

Fig. 32. Relationship between water-cement ratio and compressive strength for Types I and III portland cements at different ages. These relationships are approximate and should be used only as a guide in lieu of data on job materials.

SELECTING GOOD INGREDIENTS

Concrete ingredients consist of aggregates, water, and portland cement, plus an air-entraining agent if required due to exposure conditions.

Aggregates (sand, gravel and crushed stone) are used in concrete to provide volume at low cost. Comprising 60 to 80 per cent of the volume of concrete, they can be called a filler material. Both fine and coarse aggregates must be clean,

21119

sound, and well graded. Consideration of aggregate size for the job is important. Generally, the most economical mix is obtained by using the largest-size aggregate that is practical for the specific job. Fine aggregate should have particles ranging in size from 1/4 in. down to particles that will pass through a sieve having 100 openings to the inch.

Mixing water for concrete should be clean and free of acids, alkalies, oils, sulfates, and other harmful materials. A good rule for all jobs is that the water used for concrete should be fit to drink, or tests should be made to determine its suitability.

Portland cement of the type best suited for the job should be selected. The cement should be free of hard lumps.

Air in the form of microscopic bubbles improves the durability of concrete. Air-entrained concrete should be used where the hardened concrete is exposed to alternate freezing and thawing or where de-icing chemicals are used. It is recommended for practically all outside concrete jobs. Because air-entrained concrete improves workability, it should also be considered for most indoor jobs. To entrain air, either an air-entraining portland cement or an air-entraining agent must be used. Unless an air-entraining cement is used, enough agent must be added to a portion of the mixing water to produce the desired air content. The amount recommended by the manufacturer will, in most cases, produce the desired air content.

ALLOWING FOR MOISTURE IN SAND

The proper water-cement ratio for the kind of work or exposure condition having been selected, the next step is to consider the effect of moisture in sand.

Knowing the gross amount of water is not quite enough. It is necessary to consider the amount of water carried by the fine aggregate. The amount carried by coarse aggregate is generally so small that it can be overlooked.

It is important to determine the net amount of water to use for sands of various degrees of wetness. Otherwise, this moisture is free to react with the cement and change the water-cement ratio. Hence, the sand must be tested for water content and an allowance made.

Dry sand is seldom available for concrete work. This is material which is as dry as it would be if it were spread out in a thin layer and dried in the sun or warm air.

Most sand used on the job contains a surprising amount of water. For small jobs it is possible to estimate the amount of water in the sand by squeezing it in the hand.

Damp sand feels slightly damp to the touch but leaves little moisture on

the hands. Damp sand usually contains about 1/4 gal. of water per cubic foot (about 2 per cent by weight).

Wet sand, which is the kind usually available, feels wet and leaves a little moisture on the hands after being handled. Wet sand contains approximately 1/2 gal. of water per cubic foot (about 4 per cent by weight).

Fig. 33. If sand falls apart it is damp. Fig. 34. If sand forms a ball it is wet.

Very wet sand is dripping wet when delivered on the job and leaves more moisture on the hand than wet sand. Very wet sand carries about 3/4 gal. of water per cubic foot. When it contains large amounts of fine material, it may carry as much as 1-1/3 gal. per cubic foot (from 6 to 10 percent by weight).

Fig. 35. If sand sparkles and wets the hand it is very wet.

21121

PROPORTION THE MATERIALS

After the sand is classified as damp, wet, or very wet, the following table may be used to determine the trial proportions for any particular job:

Table 9. Trial Mix Proportions

	Gal. of water added to 1-bag batch if sand is:			Suggested mixture for 1-bag trial batches*		
	Damp	Wet Av. sand	Very Wet	Cement bags Cu.ft.	Aggregates Fine Cu.ft.	Aggregates Coarse Cu.ft.
FOR MILD EXPOSURE 7 gal. of water per bag of cement	For 1-1/2-in. max. size aggregate					
	6-1/4	5-1/2	4-3/4	1	3	4
FOR NORMAL EXPOSURE 6 gal. of water per bag of cement	For 1-in. max. size aggregate					
	5-1/2	5	4-1/4	1	2-1/4	3
FOR SEVERE EXPOSURE 5 gal. of water per bag of cement	For 1-in. max. size aggregate					
	4-1/2	4	3-1/2	1	2	2-1/4

* Mix proportions will vary slightly depending on gradation of aggregates.

USE MAXIMUM SIZE AGGREGATE PERMISSIBLE

As previously discussed, the larger the coarse aggregate the less paste will be necessary, hence the more concrete obtained per bag of cement used. This means that the most economical mix is generally obtained by using the largest coarse aggregate practical for the job.

The maximum size generally depends on the size and shape of concrete members and the amount and distribution of reinforcing steel. The maximum size of aggregate usually should not exceed:

1. One-fifth the dimension of non-reinforced member

2. Three-fourths the clear spacing between reinforcing bars or between reinforcing bars and forms, or

3. One-third the depth of non-reinforced slabs on grade.

21122

PREPARING TO MIX CONCRETE

Ways to save money or reduce labor on the job should not be overlooked.

The mixing site should be as close as practicable to the point where the concrete is to be placed. The size of the mixer depends upon the size and type of the job and the manpower available. Concrete for large flat jobs is easy to place and a large mixer will help speed up the job. The mixer should be checked for capacity, which is usually given on an attached plate.

The aggregates should be placed so that they are convenient to the mixer operators. The cement must be stored in a dry location. If it is stored outside, it should be raised above the earth and covered with a tarpaulin, polyethylene, or other suitable cover. Ample water and measuring containers should be available.

MEASURE ALL MATERIALS

All materials should be accurately measured. A pail marked on the inside at different heights to indicate quarts and gallons is handy for measuring water. On small jobs a pail may also be used for measuring cement, sand, and gravel. In mixing 1/2- or 1-bag batches, remember that a 94-lb. bag of cement contains exactly 1 cu. ft. loose volume. Aggregates are then conveniently measured in bottomless boxes made to hold exactly 1 cu. ft., 2 cu. ft., or other volumes desired.

MIXING THE CONCRETE

All concrete should be thoroughly mixed until it is uniform in appearance and all materials are uniformly distributed. This means that concrete should be mixed for at least 1 minute and preferably for 3 minutes after all materials have been placed in the mixer. There is little advantage in mixing for more than 3 minutes.

Under usual conditions, up to about 10 per cent of the mixing water should be placed in the drum before the dry materials are added. Water should then be added uniformly with the dry materials, leaving about 10 per cent to be added after all other materials are in the drum.

Accurate measurement of all materials, including water, is necessary to ensure production of uniform batches of quality concrete. Uniformity is assured by using accurate weighing or measuring equipment. Good judgment is necessary to secure concrete of proper consistency. Concrete in the mixer usually appears drier than it does after being placed.

Mixers used on the job vary in size from 1/2-cu. ft. to 2-bag mixers, or larger. Regardless of size, mixers should not be loaded above their rated capacity and they should be operated at approximately the speeds for which they are designed. If the blades of the mixer become worn or coated with hardened concrete,

21123

the mixing action will be less efficient. Badly worn blades should be replaced and hardened concrete should be removed before each run of concrete.

CLEANING EQUIPMENT

The mixer and other equipment or tools used in contact with concrete should be cleaned when necessary during use and thoroughly cleaned after use.

Mud and dirt on the frame and mixer can usually be hosed off. Periodically, it may be necessary to clean the cement film off the exterior. A weak vinegar solution (10 per cent acetic acid) is sometimes used for this purpose. Areas cleaned with acid solutions should be rewaxed.

Concrete build-up inside the drum must be prevented for top efficiency in mixing and discharging. The interior of the drum should be hosed thoroughly. However, residues of hardened cement and concrete may remain. Hard scraping or brushing may be necessary. One of the easiest ways to tear up a drum and blades is the continuous use of a heavy hammer to remove build-up. A much more satisfactory method for loosening stubborn material is to use a solution of 3 parts water to 1 part muriatic acid. Apply solution and allow about 30 minutes for penetration before using "elbow grease."

Commercially available releasing agents have proved satisfactory in reducing man-hours for cleaning mixers and concrete equipment and tools. Solvents are also available to protect implements from cement dust, concrete, and dirt adhesion.

APPLICATION

Discuss quality concrete made in small mixers.

Explain, show, and let students examine samples of dry, wet, and very wet sand.

Make a 1/10-bag mixture in mixing pan.

Show films: Concrete Example

TEST OR DISCUSSION POINTS

1. What is the objective of a properly designed concrete mixture?
2. Explain how the most economical mix can be obtained for a given exposure condition.
3. What are the proper mixes (water-cement ratios) for mild exposure? Normal exposure? Severe exposure?
4. Why is it necessary to consider the moisture content of the fine aggregate?
5. Explain how you determine if a sand is dry, damp, wet, or very wet.
6. How much moisture does wet sand contain?
7. Explain what "select good ingredients" means.
8. Why is it advisable to use the largest size aggregate practical for a job?
9. What should be considered when determining the mixing site?
10. Where should aggregates be located in relation to the mixer?
11. What effect has the quantity of mixing water on the quality of concrete?
12. What is the volume of 1 bag of cement?
13. Explain the procedure for loading a mixer.
14. Explain how a mixer should be cleaned after use.

TOOLS AND MATERIALS

Samples of dry, damp, wet, and very wet sand

PLACING CONCRETE

Preparation prior to concreting includes compaction, trimming, and moistening the subgrade, erecting the forms, and setting the reinforcing steel.

Time, transportation on the job, and methods of placing in forms are probably the most important phases of placing concrete.

TIME

Concrete must be delivered and discharged from a truck within 1-1/2 hours after water has been added to the mixture. In hot weather, or under conditions contributing to quick stiffening of the concrete, less than 1-1/2 hours should elapse. Usually it is good practice to place concrete in forms within 30 to 60 minutes after mixing. This means that the site must be ready and that ready mixed concrete trucks should not be kept waiting. If the truck is delayed, excessive mixing and hydration may cause the concrete to become stiff and difficult to place and finish. Also, the next delivery will be behind schedule.

TRANSPORTATION ON THE JOB

Methods used to move concrete from the mixer or truck to the forms will depend largely upon the job conditions. On small jobs, wheelbarrows are the usual means of transportation. However, concrete is handled and transported by many methods. These include the use of chutes, buggies operated over runways, buckets handled by cranes or cable ways, small rail cars, trucks, pumping through pipelines, and by forcing the concrete through hoses pneumatically.

Regardless of the kind of transportation used, care must be exercised to prevent segregation as the concrete is being moved. A rather stiff mix and smooth runways are usually required to prevent segregation. However, the method of handling and transporting concrete and the equipment used should not place a restriction on the consistency of the concrete. This should be governed by the placing conditions. If these permit the use of a stiff mix, the equipment should be selected and arranged to facilitate handling and transporting such a mix.

Plan the job so that the ready mix truck can get as near the job site as possible. This will save the time that would be needed to move concrete by hand methods. Remove debris and unnecessary equipment to give the truck more freedom of movement.

PLACING IN FORMS

Forms should be clean, tight, adequately braced, and constructed of materials that will impart the desired texture to the finished concrete. Sawdust, nails,

e. Avoiding reinforcement. Vibrator heads should not be held against reinforcement.

f. Caution necessary. Over-vibration or using the vibrator haphazardly can spread or tear apart forms.

APPLICATION

Discuss handling and placing concrete.
Show Slides No. 12, 13, 14, and 15 from Mr. Quality Concrete slide series.
Show film, How to Transport, Place, Finish, and Cure Quality Concrete (see film list).

TEST OR DISCUSSION POINTS

1. How much time is permitted between addition of water and concrete placement?
2. Describe some of the things that can happen when a ready mix truck is delayed from discharging a load of concrete.
3. Why should a ready mix truck get as close to a job as possible?
4. What methods are usually used to transport concrete at the job site?
5. What precautions should be observed?
6. Is it advisable to flow or drag concrete? Why?
7. Explain how to ensure consolidation of concrete after it has been placed in forms.
8. How can honeycombing and sand streaking be prevented?
9. How deep should the layers of concrete be when placed in forms?
10. When is it advisable to use drop chutes?
11. How long should concrete be vibrated to ensure consolidation?
12. What happens if the concrete is vibrated too long?

TOOLS AND MATERIALS

21127

and other debris should be removed before concrete is placed. Wood forms should be moistened before concreting, otherwise they will absorb water from the concrete and swell. Forms should also be oiled or lacquered to facilitate form removal.

Reinforcing steel should be clean and free of loose rust or mill scale at the time concrete is placed. Any coatings of hardened mortar should be removed from the steel.

Concrete should be placed between the forms or screeds as near as practicable to its final position. To consolidate the concrete, it should be mechanically vibrated or spaded as it goes into the form, then thoroughly spaded next to the forms to eliminate voids or honeycombing at the sides. At inaccessible areas, the forms can be lightly tapped with a hammer to achieve the same results. This operation makes a dense concrete surface by forcing the coarse aggregate back from the form or face. The concrete should not be overworked while it is still plastic because too much water and fine material will be brought to the surface. This may later lead to scaling or dusting.

In slab construction, placing should be started around the perimeter at the far end of the work so that each batch will be dumped against previously placed concrete. The concrete should not be dumped in separate piles and the piles then leveled and worked together. Nor should the concrete be placed in large quantities (big piles) and allowed to run or to be worked over a long distance to its final position. Honeycombing and segregation may occur as the mortar tends to flow ahead of the coarser material. Water should be prevented from collecting at the ends and corners of forms and along form faces.

If concrete is placed in layers not more than 12 to 18 in. thick along a form, good uniformity will be obtained. Each layer should be thoroughly consolidated before the next is placed.

In some work, such as beneath openings in walls, it is necessary to move the concrete horizontally within forms. The horizontal distance should be minimized as much as practicable.

When concrete is placed in tall forms at a fairly rapid rate there is likely to be some bleeding of water to the top surface, especially with non-air-entrained concrete. Bleeding can be reduced by placing more slowly and by using concrete of a stiffer consistency. When practicable, the concrete should be placed to a level about a foot below the top in high walls; an hour or so should be allowed for settling. Concreting should be resumed before setting occurs to avoid formation of cold joints. It is good practice to overfill the form several inches and cut off the excess concrete after it has partly stiffened.

The old rule that "good concrete is placed, not poured" is still very true and should be kept continuously in mind. Also, concrete should be placed where

21128

needed; do not flow, push, or drag it into place. When using buggies, wheelbarrow, etc., dump into the face of previously placed concrete; don't dump away from it.

DO NOT ADD EXCESS WATER AT THE JOB SITE

Ready mixed concrete is usually delivered after it has been accurately designed for a specific job. Addition of water will seriously affect all of the desirable properties of the finished concrete such as durability, strength, and watertightness. Even so, occasionally you see jobs where excessive water is being added so that concrete can be flowed into forms without working it. This is a practice that should never be allowed. Don't expect to get good concrete into place without some work.

USING A DROP CHUTE

The use of a chute is recommended when fresh concrete must be dropped more than 3 or 4 ft. If concrete is allowed to strike one side of the form and bounce off, it will separate and cause stone pockets and sand streaking. Drop chutes are also sometimes used to prevent incrustation of dried mortar on reinforcement and forms. In thin sections, drop chutes of rubber or metal should be used. In narrow wall forms, the metal drop chutes are made rectangular to fit between reinforcing steel. Drop chutes are available in several lengths or in sections which can be hooked together so that the length can be adjusted as concreting progresses. Fig. 49 shows a drop chute with hopper.

Fig. 49. A rectangular drop chute with hopper at top for placing concrete in narrow walls.

CONSOLIDATING CONCRETE IN FORMS

The most common methods for consolidating concrete in forms are by hand spading or vibration. Proper use of vibrators makes possible placement of stiff, harsh mixes that could not be placed and consolidated readily by hand. However, mixes that can be consolidated readily by hand should not be vibrated as they are likely to segregate under this action. In many cases, the slump can be less than one-half that required for hand placing and in most cases it can be reduced at least one-third.

VIBRATORS ARE A GREAT AID

Immersion-type vibrators, commonly referred to as spud vibrators, are excellent tools to consolidate fresh concrete in walls or other formed work. The spud vibrator is a metal tube-like device which vibrates at several thousand cycles per minute. It is usually powered by gasoline, air, or electricity. When inserted in the concrete for 5 to 15 seconds, the spud vibrator consolidates and improves the surface next to the forms.

Vibrators are excellent tools for placing dry mixes. However, handle vibrators carefully in wet mixes, or too much water and fine sand will be brought to the surface of the concrete. Systematic vibration will give concrete adequate consolidation, but never over-use them. Vibrators should not be used to move concrete horizontally since this practice results in segregation. Leaving a vibrator immersed in concrete after the paste accumulates over the head results in non-uniformity. The length of time that a vibrator should be left in the concrete is a function of the slump of the concrete; high slump requires little or no vibration. Vibrator heads should never be held against reinforcement. Over-vibrating, or using the vibrator haphazardly, can spread or tear apart forms.

Form vibrators may be attached to the exterior of forms. They are especially useful for consolidating concrete in thin-walled members and where metal forms are used.

MICROCOPY RESOLUTION TEST CHART

NATIONAL BUREAU OF STANDARDS-1963-A

FINISHING CONCRETE SLABS

Choice of concrete finish depends on the final use of the completed job and the effect desired. Various colors and textures, such as exposed aggregates, may be used. Some surfaces may require only striking off to proper contour and elevation, while in other cases a broom, float, or trowel finish may be specified. To finish concrete properly it is essential to know the specific operations required.

CONSOLIDATING

Consolidating concrete is necessary to give a uniform, plastic mass. It eliminates stone pockets and large air voids. Many methods are employed for consolidation. Probably the most common method is use of a strike-off board or straightedge.

Other tools for consolidating include tampers, rollers or roller screed, vibrating screed, and jitterbug or jitterbug crawler.

Tampers and jitterbugs should be used sparingly and only when consolidation cannot be accomplished readily by hand. Usually this would apply to concrete having a low slump; otherwise the concrete will tend to segregate.

STRIKING OFF

Striking off (sometimes called screeding) is a leveling operation that removes humps and hollows and gives a true, even concrete surface. Often consolidation and strike-off are combined into a single operation by the use of the strike-off rod or straightedge. This is usually a specially prepared tool, but in an emergency a 2x4 or 2x6 that is 1 to 2 ft. longer than the section being finished may be used. The surface is struck off or rodded by moving the straightedge back and forth with a sawlike motion across the top of the forms or screed and advancing forward a short distance with each movement. A small amount of concrete should always be kept ahead of the straightedge to fill in low spots and maintain a plane surface. Vibrator screeds, roller screeds, and mechanical screeds are also used for screeding or striking off.

Immediately after screeding, concrete should be darbied or bull-floated before any free water has bled to the surface. The bullfloat is very handy because it has a long handle and is easy to use on wide slabs.

Darbying and bullfloating eliminate the ridges and voids left by the strike-off operation. This also helps embed large aggregate beneath the surface and brings sufficient mortar to the surface in preparation for other finishing operations. Care must be taken during this operation to avoid overworking the surface.

Sometimes the concrete is left without further finishing, but for most jobs strike-off is followed by one or more of the following operations.

EDGING AND JOINTING

When all bleed water and water sheen have left the surface (the glossy appearance is gone) and the concrete has started to stiffen, it is time for the remaining finishing operations. All open edges should be rounded off with an edger to prevent spalling. The edger should be run back and forth until a finished edge is produced. The concrete finisher should make certain that all coarse aggregate particles are covered and that the edger does not leave too deep an impression in the top of the slab. Otherwise, the indentation may be difficult to remove with subsequent finishing operations. Initial edging should be done with a wide flange tool having a radius of 1/8 in. or less. Joints with greater radii are difficult to maintain.

The marks left by the edger and jointer should be removed by floating unless such marks are desired for decorative purposes, in which case the edger or jointer should be rerun after the floating operation. If necessary, tooled joints and edges should be rerun before and after troweling to maintain uniformity or to remove kinks.

Concrete expands and contracts slightly due to temperature differences. It may also shrink as it hardens. Control joints, often called dummy or contraction joints, are cut across each strip to control cracking. They do not extend completely through the slab but are cut to a depth of 1/4 to 1/5 of the slab thickness, thus making the slab weaker at this point. If the concrete cracks due to shrinkage or thermal contraction, the crack usually occurs at this intentionally weakened section.

Control joints should be cut soon after the concrete has been placed in order to work the larger pieces of coarse aggregate away from the joint. A simple way to cut this type of joint is to lay a board across the fresh concrete and cut the joint to the proper depth with a groover having a 3/4- or 1-in. bit. Sometimes a finisher will use a brick mason's trowel to cut the joint approximately 1/4 to 1/5 the slab depth. A groover is then used to finish the joint. Control joints are generally placed 10 to 15 ft. apart on floor slabs, driveways, and feeding floors. They are placed 4 to 5 ft. apart on sidewalks.

Since the development of special concrete saw blades, sawing contraction joints is becoming common. The proper time to saw joints is generally 4 to 12 hours after the concrete has been placed and finished. A sawed joint is clean and attractive and works well when cut to the proper depth. On larger jobs a special mobile concrete saw is used. On smaller jobs, such as sidewalks and driveways, a portable electric hand saw may be used. The operator must be careful to keep the saw blade straight so that it will not shatter.

floating is necessary after the concrete has partially hardened so that a desired permanent finish can be produced. It is used to produce gritty, non-slippery surfaces that wear well, are attractive, and provide good footing.

TROWELING

Where a smooth, dense surface is desired, floating is followed by steel troweling. This operation should be delayed as long as possible. Too long a delay, of course, will result in a surface that is too hard to finish with a trowel, but the tendency in most cases is to trowel the surface while the concrete is too soft and plastic. Excessive troweling at this stage may cause crazing and may result in a surface having less wear resistance.

Spreading dry cement on a wet surface to take up excess water is not a good practice. Such wet spots should be avoided insofar as possible by adjustments in the grading, mix proportions, and consistency. When wet spots do occur, finishing operations should be delayed until the water either disappears or is removed with a squeegee.

This first steel troweling should be sufficient to produce a smooth surface free of defects. Whether troweling is by power or hand, the trowel blade must be kept as flat against the surface as possible. If the trowel blade is tilted or pitched at too great an angle, an objectionable "chatter" or "washboard" surface will result. For first troweling a new trowel is not recommended. An older trowel that has been broken in can be worked quite flat without the edges digging into the concrete.

A second troweling is applied after the concrete has become hard enough that no mortar adheres to the edge of the trowel and a ringing sound is produced as the trowel passes over the surface. Additional trowelings may be desirable depending on the traffic and exposure conditions. During the final troweling, the trowel should be tilted slightly and heavy pressure should be exerted to compact the surface thoroughly. There should be a lapse of time between successive trowelings to permit concrete to increase its set.

Power troweling should be delayed until the concrete is firm. Power trowels are being widely used to finish concrete. Again, premature troweling must be avoided. The concrete should be hard enough to hold the power trowel.

PATTERNED AND TEXTURED FINISHES

A variety of patterns and textures can be used to produce decorative finishes for concrete slabs. Patterns are formed by using divider strips or by grooving the surface just before the concrete hardens.

An exposed-aggregate finish provides a rugged non-skid surface. Selected aggregates, usually of uniform size, 3/8 in. or larger, are evenly distributed on the

21135

surface immediately after the slab has been darbied. The aggregate particles are embedded in the concrete by lightly tapping them with a darby or a flat board. After the concrete hardens sufficiently to support a finisher on kneeboards, the surface should be hand-floated with a magnesium float or darby. The aggregate is then exposed by simultaneously brushing and flushing with water. On large jobs a reliable retarder may be sprayed or brushed on the surface, but on small jobs this may not be necessary. Timing is important, so test panels are usually made to determine the correct time for exposing the aggregate without dislodging the particles.

FINISHING AIR-ENTRAINED CONCRETE

Air entrainment gives concrete a somewhat altered consistency that requires a slight change in finishing operations from those used with non-air-entrained concrete.

Air-entrained concrete contains microscopic air bubbles that tend to hold in suspension all the materials in the concrete, including water. This type of concrete requires less mixing water than non-air-entrained concrete but still has good workability with the same slump. Since there is less water--and it is held in suspension--little or no bleeding occurs. With no bleeding, there is no waiting for the evaporation of free water from the surface before starting floating and troweling. This means that floating and troweling should usually be started sooner--before the surface becomes too dry or tacky. If floating is done by hand, the use of an aluminum or magnesium float is essential. A wood float drags and greatly increases the amount of work necessary to accomplish the same result. If floating is done by power, there is practically no difference between finishing procedures for air-entrained and non-air-entrained concrete, except that floating may be started sooner on the air-entrained concrete.

Practically all horizontal surface defects and failures are caused by finishing operations performed while bleed water or excessive surface moisture is present. Better results are generally accomplished, therefore, with air-entrained concrete.

21136

APPLICATION

Discuss the "why, when, and how" of finishing flat concrete work. Show slides 16, 17, 18, 19, 20, 36, and 37 from Mr. Quality Concrete slide set. Show film

How to Make Decorative Patio Floors for Outdoor Living (see film list).

TEST OR DISCUSSION POINTS

1. What is meant by finishing concrete?
2. Why is concrete consolidated? How is this done?
3. Explain why striking off is necessary. How is striking off performed?
4. Why should a small amount of concrete be kept ahead of the straightedge at all times?
5. What is the purpose of floating?
6. When is the right time to start floating?
7. What are the tools used for floating?
8. When should edging and jointing be performed?
9. What are two other names for control joints?
10. Why are control joints necessary?
11. What should be the spacing for control joints in slabs? Sidewalks?
12. How deep should control joints be cut?
13. If a saw is used, how soon should control joints be cut?
14. Explain the purpose of final finishing.
15. When should final finishing be started?
16. How can excessive surface water be removed from slabs?
17. What are some methods for obtaining a desired surface texture?
18. Why should a steel trowel be held as flat as possible for the first troweling?
19. Why is it best to use a broken-in trowel for first troweling?
20. Why is air-entrained concrete better?
21. Why is it necessary to use an aluminum or magnesium float on air-entrained concrete?
22. Why should metal tools be used only for low-slump concrete?

CURING CONCRETE

Concrete hardens because of hydration, the chemical reaction between portland cement and water. Properties of concrete such as durability (resistance to freezing and thawing), strength, watertightness, wear resistance, and volume stability improve with age as long as temperatures are favorable and moisture is present to hydrate the cement.

Approximately three gallons of water are necessary to hydrate each bag of cement. Additional water is required, however, to make it possible to properly place the freshly mixed concrete. Excessive evaporation of water from newly placed concrete can cause the cement hydration process to stop at an early age. To prevent this loss of water, the concrete should be protected and curing started as early as possible. A rapid loss of water also causes concrete to shrink, thus creating tensile stresses at the drying surface. If these stresses develop before the concrete has attained adequate strength, plastic shrinkage cracks may result.

EFFECT OF CURING

All the desired properties of concrete are improved by proper curing. Soon after the concrete is placed, the increase in strength is very rapid (3 to 7 days). The strengthening then continues slowly for an indefinite period. Concrete which is moist cured for 7 days is about 50 per cent stronger than that which is exposed to dry air the entire period. If the concrete is kept damp for one month, the strength is about double that of concrete exposed only to dry air.

METHODS OF CURING

Concrete may be kept moist by a number of curing methods. They can be classified as (1) supplying additional moisture to concrete, and (2) preventing loss of moisture from concrete by sealing the surface. Following is a discussion of the methods used.

Water curing by flooding, ponding, or mist spraying, is widely used. It is the most effective of all known curing methods, in terms of preventing evaporation of mix water, but is not always practical because of job conditions. On flat surfaces such as pavements, sidewalks, and floors, the flooding or ponding method may be easily accomplished. A small dam of earth or other water-retaining material is placed around the perimeter of the surface and the enclosed area is kept flooded with water. Continuous sprinkling with water is also an excellent method of curing. If sprinkling is done at intervals, the concrete must not be allowed to dry between applications of water. A constant supply of water prevents the possibility of "crazing" or cracking caused by alternate wetting and drying.

21138

Water retaining methods involving use of coverings that are kept continuously wet such as sand, burlap, canvas, or straw. When concrete is cured by one of these methods, the entire concrete surface, including exposed edges or sides, must be covered--for example, the sides of pavements and sidewalks where the forms have been removed. Materials used for water retention must be kept damp constantly during the curing period. If drying is permitted, excessive moisture may be absorbed by the cover itself. In vertically formed concrete, a simple way to prevent the concrete from drying out is to leave the forms in place.

Mechanical barriers of waterproof paper or plastic film seal in the water and prevent evaporation. One important advantage of mechanical barriers is that periodic additions of water are not required. These materials should be applied as soon as the concrete has hardened sufficiently to prevent surface damage. The widest practicable width of material should be used. Edges of adjacent sheets should be overlapped several inches, then tightly sealed with sand, wood planks, pressure sensitive tape, mastic, or glue.

An added feature of mechanical barriers is that they provide some protection against damage from subsequent construction activity as well as protection from the sun.

In some cases, plastic films may cause discoloration of hardened concrete. This may be especially true when the concrete surface has been steel troweled to a hard finish. This is also true for exterior or exposed concrete. When discoloration is objectionable, some other curing method is advisable.

Chemical membranes can be sprayed on to cure concrete. Liquid membrane-forming curing compounds retard or prevent evaporation of moisture from concrete. They are effective curing materials when used correctly. The application should be made immediately after the concrete has been finished. If there is any delay, the concrete should be kept moist until the membrane is applied. Membrane curing compound should not be applied when there is free water on the surface, because the water will be absorbed by the concrete and the membrane broken. Nor should the compound be applied after the concrete has dried out since it will be absorbed into the surface of the concrete and a continuous membrane will not be formed. The correct time to apply the membrane is when the water sheen disappears from the surface of the finished concrete. Adequate and uniform coverage of curing compounds is essential. In most cases two applications are required. Chemical membranes are suitable not only for curing fresh concrete but also for further curing of concrete after removal of forms or after initial moist curing.

Curing compounds are of four general types: clear or translucent, white pigmented, light gray pigmented, and black. During hot, sunny days, white pigmented compounds are most effective since they reflect the sun's rays, thereby reducing the concrete temperature. Curing compounds can be used to prevent bond between hardened and fresh concrete. Consequently, they should not be used if bond is necessary. For example, a curing compound should not be applied to the base slab of a two-course floor since it may prevent the topping from bonding.

21139

Similarly, some curing compounds affect the adhesion of resilient flooring materials to concrete floors. Curing compound manufacturers should be consulted to determine if their product is in this category.

GENERAL CURING REQUIREMENTS

As a general rule, concrete should be cured for at least three days and preferably for a week after it is placed. The time depends on the concrete's temperature. When the temperature is 70 deg. F. or above, cure the concrete for at least 3 days. When the concrete temperature is 50 deg. F. or above, cure for at least 5 days.

The length of time that concrete should be protected against loss of moisture depends upon several factors--cement content, mix proportions, required strength, size and shape of the concrete mass, weather, and future exposure conditions. This period may be a month or longer for lean concrete mixtures used in massive structures such as dams, but it may be only a few days for richer mixes. Since all the desirable properties of concrete are improved by curing, the curing period should be as long as practicable in all cases.

Concrete should be protected so that moisture is not lost too rapidly during the early hardening period. Concrete should be kept at a temperature that is favorable for hydration. The most favorable temperature range for curing concrete is from 55 to 73 deg. F. At higher temperatures, hydration takes place more rapidly, but the concrete doesn't attain its full strength. Hydration proceeds at a slower rate when temperatures are below 70 deg. F. There is practically no chemical action between cement and water when the temperature is near freezing. At 33 deg. F. it takes more than three times as long to develop a given strength as it does at 70 deg. F. No gain whatever can be expected while concrete is frozen, but hydration will be resumed after it is thawed, provided suitable curing is applied. However, freezing within the first 24 hours is almost certain to result in permanent injury to the concrete.

A thought to keep in mind: The longer concrete is moist cured, the better its durabilility, strength, watertightness, wear resistance, and volume stability.

EPCTS

21140

APPLICATION

Discuss the "why, when, and how" of curing concrete.
Show slides 21, 22, 23, and 24 from Mr. Quality Concrete slide set.

TEST OR DISCUSSION POINTS

1. What causes concrete to harden?
2. Why does all concrete need to be cured?
3. About how many gallons of water are required to hydrate each bag of cement?
4. Why does concrete usually contain more water than necessary for hydration?
5. Concrete which has been moist cured for 7 days is about 50 per cent stronger than that which is kept in dry air the entire period.
6. If concrete is kept moist for 28 days, how would its strength compare with the strength of uncured concrete?
7. Explain some of the methods used for curing.
8. Can discoloration result from using mechanical barriers for curing?
9. Is discoloration always objectionable?
10. Are there situations where chemical membranes should not be used for curing? Why?
11. What is the general curing time requirement when the concrete is above 70 deg. F.?
12. What is the general curing time requirement when the concrete is above 50 deg. F.?
13. What is the most favorable temperature range for curing concrete?
14. What will happen if concrete freezes during the first 24 hours?

21141

REINFORCEMENT FOR CONCRETE

Reinforcement is the term used to describe the steel bars or small or large welded wire fabric positioned in concrete to increase its tensile strength.

Concrete has great strength in compression--that is, it can support great loads that are placed directly upon it. However, steel bars or other metal reinforcement is required in some structures to increase the ability of concrete to resist stresses or forces that tend to bend or pull it apart. The compressive strength of concrete is about 10 times its tensile strength. See Fig. 51.

When reinforcement is used in concrete, the reinforcement acts to withstand tensile pull. Depending on how much reinforcement is used, the tensile strength can be made to equal or exceed the compressive strength. See comparison in Fig. 52.

Fig. 51. Comparison of the compression and tension properties of nonreinforced concrete.

Thousands of pounds COMPRESSION

Hundreds of pounds TENSION

Fig. 52. Comparison of the compression and tension properties of concrete when reinforcing is used.

Thousands of pounds COMPRESSION

Thousands of pounds TENSION

KINDS OF REINFORCEMENT

Through the years, many materials have been tried as reinforcement in concrete. Today steel is universally accepted and used. One important advantage of steel is that it has nearly the same contraction and expansion characteristics, due to temperature changes, as concrete.

Reinforcing steel can be purchased in the form of reinforcing bars or as welded wire fabric. Bars may be either smooth or deformed. Smooth bars are

21142

usually of small diameter. Deformed bars have lug-like ridges that increase the bond between the concrete and steel. Bars come in standard sizes and are properly designated by number. The size of bar to use depends on the amount of tensile force the concrete will carry. Table 16 gives the standard bar sizes up to 1-in. diameter, the steel area that each provides, and the weight of 100 ft. of bar. Larger bars are also made for extremely heavy construction.

Table 16. Size, Area, and Weight of Reinforcing Bars

Bar number	Bar diameter, in.	Bar area, sq.in.	Approximate weight of 100 ft.
2	1/4	0.05	17
3	3/8	0.11	38
4	1/2	0.20	67
5	5/8	0.31	104
6	3/4	0.44	150
7	7/8	0.60	204
8	1	0.79	267

Bars are usually supplied by the mill in 60-ft. lengths. Local building materials suppliers ordinarily stock 20- or 40-ft. lengths.

Welded wire fabric is made in many types and sizes. The most common type used in light construction has wires spaced at 6-in. centers both ways; 6-, 8-, and 10-gage fabric is commonly available. The type of fabric is usually referred to as "6 x 6 - 10 - 10." This is usually spoken "six-six-ten-ten." This expression indicates that the fabric has longitudinal wires of No. 10 gage, spaced at 6-in. centers, and transverse wires of No. 10 gage, spaced at 6-in. centers. Table 17 shows the area of steel provided by the three sizes and the weight of 100 sq.ft. of the fabric. Welded wire fabric is used for jobs that require relatively light reinforcement.

Table 17. Steel Area and Weight of Three Sizes of Welded Wire Fabric

HOW REINFORCEMENT WORKS

Tensile forces are created in a structure in many ways. Concrete can be subjected to a straight tensile pull, to bending, or to temperature and moisture changes.

In many construction uses, concrete is subjected to a straight tensile pull. Round structures such as water tanks and farm silos are the most common examples. Pressures within the tank tend to push the two halves apart, as shown in Fig. 53. Reinforcing steel in the wall holds the tank halves together. Steel is needed around the entire tank wall since pressures act in all directions, not just in the directions shown in Fig. 53.

Fig. 53. Diagram illustrates the use of steel reinforcement to overcome the outward pressures within a round structure.

In round structures of this kind, the steel is usually placed near the center of the wall cross-section, preferably slightly outside the centerline.

In concrete beams, only part of the beam contains tensile forces. In this case, location of the reinforcement is just as critical as the amount used to resist bending loads. In concrete lintels across door or window openings or in a beam, for example, reinforcement is placed near the lower side, as that is the side which tends to pull apart when the beam is loaded.

The lintel must be able to carry the load of the wall, floor, or roof that rests on it. The dotted lines in Fig. 54 show a greatly exaggerated picture of the bending that occurs in the lintel. Note that the ends of the beam at the top surface have moved closer together. The ends at the bottom surface have moved apart. Thus, the concrete at the top of the lintel has been compressed; that at the bottom has been stretched. Since concrete cannot survive much stretching or tension, reinforcing steel must be placed near the bottom of the lintel.

Fig. 54. An illustration showing the location of the compressive and tensional forces in a simple beam.

21144

TEMPERATURE AND MOISTURE CHANGES

Concrete, like other construction materials, expands and contracts with changes in temperature and moisture. Reinforcement is sometimes used to reduce cracking due to these changes. While welded wire fabric will not prevent formation of the cracks, it will distribute them and generally make them smaller. In some concrete work a system of jointing the slab into 10- to 15-ft. squares is usually more economical than using reinforcement if the sole purpose is to control temperature and shrinkage stresses.

PLACEMENT OF STEEL

The size, location, and spacing of reinforcement usually are determined in advance by experienced engineers. However, the important operation of placement is performed on the job.

In general, all reinforcement should be placed so that it is protected by an adequate coverage of concrete (see Table 18).

Table 18. Concrete Protection for Reinforcement*

Members	Minimum concrete protection
1. Footings	3 in.
2. Concrete surface exposed to weather	2 in. for bars larger than No. 5, 1-1/2 in. for No.5 bars and smaller
3. Slabs and walls	3/4 in.
4. Beams and girders	1-1/2 in.
5. Joists	3/4 in.
6. Columns	Not less than 1-1/2 in. or 1-1/2 times the maximum size aggregate
7. Corrosive atmospheres or severe exposures	Protection shall be suitably increased

*American Concrete Institute ACI 318, "Building Code Requirements for Reinforced Concrete."

SPLICING REINFORCEMENT

Because reinforcing steel carries tensile load in concrete, the steel must be lapped at a splice. The overlap distance for deformed bars should always be at least 24 bar diameters, with a minimum lap of 12 in. (see Fig. 55). Smooth bars must be lapped even greater distances.

21145

Welded wire fabric is spliced by lapping at least one full stay spacing plus 2 in. For a 6x6 fabric this would require at least an 8-in. lap.

Fig. 55. Bars must be overlapped to transfer tensile stress.

SLAB REINFORCEMENT

Reinforcement is often used in floor slabs for homes under the following conditions:

1. If load-bearing partitions are more than 4 ft. from the center axis of the slab.

2. If the slab is placed on fill more than 2 ft. deep, or if more than 10 per cent of the area within the foundation wall has been excavated and backfilled.

3. If heat ducts or pipes are embedded in the slab.

4. If unheated slabs are longer than 30 ft.

The use of reinforcement (bars or welded wire fabric) will not assure the prevention of cracks. However, it may reduce the size of the opening if a crack does occur. The reinforcing steel should be placed 1 in. from the top of the slab and held in this position. If welded wire fabric is used, it should not be placed on the subbase and pulled up with a rake or hook because it is virtually impossible to control its position by this method.

If the floor does not contain reinforcement but does have warm air ducts, the area over the ducts should be reinforced. Use a 6x6x10-gage fabric and extend it 18 in. past the point where the slab thickness returns to normal.

CONCRETING AROUND STEEL

Concrete should be placed around and under all reinforcement and embedded fixtures. Tapping the form with a rubber or wood mallet or any similar practical method may be used to make the concrete settle around and under reinforcement.

GENERAL RULES FOR STEEL REINFORCEMENT

The following represent general rules that should be followed:

1. Use only clean steel free from rust, paint, scale, etc.

21146

2. Place steel as recommended in Table 18, "Concrete Protection for Reinforcement."

3. Limit aggregate size used in concrete to 3/4 of the minimum spacing between reinforcing bars or between reinforcement and forms.

4. Lap all bars a minimum of 24 times their diameter and never less than 12 in.

5. Place reinforcement where concrete will be in tension.

REINFORCED CONCRETE ACCESSORIES

Contractors' supply houses and concrete accessory manufacturers stock a wide range of materials to help ease the job of steel placement. Bar chairs, form ties, bar spacers, slab bolsters, and many other devices are available. Fig. 56 shows some of the most common accessories.

Fig. 56. Three of the more common devices that are available for easing the job of steel placement.

NEW DEVELOPMENT IN REINFORCEMENT

In the past few years, great strides have been made in reinforced concrete technology. Reinforcing bars are constantly being improved. The deformed bars used today bond to the concrete much more firmly than those used only a few years ago. This improvement was achieved by changing the shape of the deformity or lugs. One of the most recent developments is high-strength steel reinforcing bars. When high-strength steel is used, the amount of reinforcing steel can be reduced.

21147

APPLICATION

Discuss and illustrate by drawings on chalkboard the purposes of reinforcing concrete and methods for placing reinforcing bars and fabric.

TEST OR DISCUSSION POINTS

1. What is reinforcement?
2. What is the difference between tension and compression?
3. Is concrete considered to be strong in compression?
4. Bar diameters are designated by number. What is the number of a 1/2-in.-diameter bar?
5. What is the diameter of a No. 8 bar?
6. What are the three gages of fabrics commonly available?
7. When is welded wire fabric used?
8. Which side of a beam or lintel tends to pull apart when the concrete member is loaded--the top or the bottom?
9. Where should steel be placed to counteract the load applied to a beam or lintel?
10. Most construction materials expand and contract with changes in temperature and moisture. Is this true of concrete?
11. Explain the rule for lapping bars.
12. Explain the rule for lapping wire fabric.
13. Explain how concrete can be worked around and under all steel reinforcement.
14. What determines the minimum distance steel should be placed from an outside surface?
15. What is a bar chair?
16. What is a slab bolster?

Field Engineering and Inspection of Forms for Concrete

1. Purpose of Forms

A. The primary purpose of the concrete form is to hold the plastic concrete in place during the setting period. Final appearance of the concrete structure is largely dependent upon the quality of the form work.

B. Forms also serve to prevent the loss of moisture from the concrete during the curing period. In cold weather forms provide some insulation to help retain the heat.

2. Form Building Material

A. Wood remains the major form building material because it is least expensive and it is easily worked.

(1) Dimension lumber is used to form structural members.

(2) Plywood sheathing is most commonly used as the face against which concrete is to be placed.

(3) There are features which limit the uses of wood. It is among the weaker of the form building materials -- it serves well where a form is used once and then dismantled and rebuilt, but it does not have sufficient strength to withstand repeated handling and reuse as a form unit.

A disadvantage of wood sheathing is that it can be easily scarred and gouged. There is danger of this both when handling the forms and during concrete placement. A type of blemish called vibrator burns, which results from hitting forms with the vibrator during concrete placement is particularly damaging.

(Drawings of typical wooden forms are included.)

B. Steel has a strength advantage over other form building materials, and in addition it does not swell nor warp in a wet environment. Its ability to withstand rehandling is its most important advantage.

(1) Steel is finding considerable use in forming structural members -- especially where long spans are required. It is also used in patented stringers and shoring.

(2) Steel faced forms are generally limited to specialty work where a formed detail is to be repeated many times, such as in a concrete railing.

Steel faced flat panels, for assembly into wall forms, and steel pans, for forming waffle or beam and girder floor systems, are other uses of this material.

(3) Steel, however, has some features which limits its use. This is especially true in form facing.

(a) Concrete will adhere to a steel surface unless it is treated or oiled.

(b) Thin sheets of steel, while high in resistance to failure, are weak in resistance to bending deflections. Steel plate thick enough to overcome this would be too heavy to handle economically. The difficulty is accentuated because concrete surfaces cast against steel plates have a glossy surface which reflects every wrinkle and dent.

(c) Plastic concrete will penetrate seemingly tight joints in steel forms and, by expanding, force the plates further apart with each form reuse. This can be prevented only by seal welding the joints or by opening and cleaning the joints periodically.

(d) Versatility in the reuse of steel forms is lost because new tie bolt holes are difficult to make and old holes are extremely difficult to patch satisfactorily.

(e) Installation of hardware, inserts, bolts, nailer strips, chamfer, joint material, etc., are very difficult to hold accurately in position in steel forms. Actually, the inability to fasten these odds and ends into the steel form is one of their major drawbacks and must be considered at an early planning stage.

C. Fiberglass and epoxy resin is being used in specialized forms. It has the advantage over steel plates or plywood sheets in that it can be molded to surfaces curved about two intersecting axes.

D. A heavy cardboard tube is often used for forming circular columns and concrete piles.

3. Planning

If the form work is at all complicated, there must be a planning stage. It is usually advantageous to make sketches or drawings of the form detail and to distribute these so that they can be checked by the engineering inspector, subcontractors, etc. Plans are also needed for ordering form building material and hardware for the carpenter shop or saw table foreman and, of course, for the final erection crew.

4. Strength

A. Forms must support the weight and withstand the fluid pressures of the enclosed concrete. Concrete weighs about 150 pounds per cubic foot. During placement by modern methods, where it is consolidated with high frequency vibrators, full fluid pressures will be developed and must be provided for. After concrete has taken its initial set, usually within one to one and one-half hours, additional fluid pressures are no longer transmitted through it.

21150

Forms should also be designed to withstand live loads that can be expected during concrete placement.

Horizontal forms must withstand the additional weight of the placing crew and equipment -- such as runways and buggies. Some form designers add one inch to the deck thickness when determining the weight to include the live load.

Wall forms should be capable of withstanding a horizontal wind load of at least 10 pounds per square foot.

Horizontal live loads on falsework are assumed at 3 to 5% of the supported weight.

B. If the final concrete surface will be exposed and visible to the eye, the deflection of the form and not its ultimate strength will be the major factor in the form design.

Concrete pressures always cause form deflections and the appearance requirement will determine what deflections can be tolerated in each case. It is common to limit this to about 1/300 -- this means that each element of the form cannot deflect more than 1/300th of its unsupported span.

As an example, tests have shown that when 5/8 inch plywood is laid across studs on 12 inch centers with the grain of the outer plywood layers normal to the studs, the plywood will deflect 1/300ths of the 12 inch span when under a load of 750 lbs. per square foot. In warm weather this pressure would be produced by placing concrete at a rate of five foot of depth increase per hour. The failure strength of the plywood would withstand several times this much pressure.

If the grain of the outer ply of the plywood were running in the other direction, that is, parallel to the studs, then the studs should be only 6 inches apart to meet the same deflection requirements.

Forms for thin walls and columns present the greatest problem from concrete fluid pressures, because with their small volumes, there is the greatest temptation to fill them rapidly.

C. Form Continuity is probably the most important factor in quality form building. It is necessary to maintain continuous rigidity throughout the form unit.

(1) Where good visual wall lines are to be maintained, it is necessary that stiff continuous members be incorporated in the forms near and parallel to the line locations. Stiff continuous top plates will give good top of concrete wall alignments. Along the top of sloping walls continuous plates or wales should be parallel to the sloping top of the wall.

(2) Continuity of some stiff members across plain surfaces is also necessary. This becomes increasingly important as the trend is toward small

form panels. Continuous studs, wales, and strong-backs or something equivalent must be incorporated into the form.

(3) In falsework, a system of continuous stiff mud-sills, cap-beams, and stringers can give a very effective mat action which will minimize the hazards of unequal settlement over poor foundation areas.

(4) It is good practice to stiffen column forms and girder soffit forms with continuous two-inch lumber.

5. Units of Construction

A. Concrete footings are seldom visible after a structure is completed. A high quality form in this case is not necessary. It is usual to permit considerable tolerance in dimensions and quite frequently forms are omitted entirely. Care is taken in making the excavation and concrete is placed directly against the earth walls.

The structural qualities of a footing, however, are important. The positioning of the reinforcing steel must be accurate, and it must be securely held in place. The template that holds the wall or column steel dowels must be firmly installed.

B. Most concrete structure walls are exposed to view and good quality form work is required -- some are important architectural elements and demand precision work.

(1) Contractors frequently use pre-built panel forms. Special attention must be paid to getting continuity between the units. Off-setting of the panels, when subjected to the concrete pressures, will cause surface blemishes which are nearly impossible to correct.

(2) Metal tie rods or bolts are used to resist pressure across the wall. There are many types of these on the market -- it is seldom wise to exceed the safe load recommended by their manufacturer. It is usually necessary that at least part of the rod be removed and the resulting hole in the concrete patched as a final operation. Occasionally, special water-proofing is also required.

Twisted wire should not be used as form ties except in very minor work. They cannot support even minor pressures without yielding, and removing the wire below the concrete surface damages the concrete.

(3) Steel straps, of the type used in packaging, are sometimes utilized in form construction where tension ties are required. They can be pulled tight and work well when used outside the form -- they can seldom be used through the concrete because of the difficulty of cutting the metal back from the concrete face.

Occasionally it is necessary to form only one side of a wall and to pour the opposite face against an existing earth or concrete surface. In these cases it is seldom possible to use ties through the wall and concrete

pressures must be held by placing struts against the form. This is a precarious arrangement and should be done with caution. If the struts are angled, they may have a strong tendency to lift the form when loaded. It is necessary to place the concrete in such walls slowly.

(4) A spreader of some type is necessary to hold the wall forms apart during the construction phase. Most manufactured wall ties perform this function too. Check to be sure their use will result in the full planned wall thickness. Occasionally, careless contractors use spreaders 1/4 inch short, assuming forms will spread during concrete placement.

Precast concrete spreaders are occasionally used and generally with excellent results. They are held in place by wiring to the reinforcing steel.

Temporary wood spreaders that must be removed during the concrete pour are a poor solution. Some are invariably overlooked during the pour and must later be chipped out of the finished concrete wall.

(5) It is good practice to place strong-backs at intervals along the wall forms. The forms will be aligned at these locations. They also afford a margin of safety needed when form ties are overloaded.

(6) Where one face of a wall is on a batter, the wall ties will not completely neutralize the fluid pressure forces. Additional tieing or bracing is required. For instance, a wall that is appreciably thicker at the bottom than at the top will tend to lift and must be tied down.

(7) Form corners must not only be constructed grout tight, but they must remain tight while under the concrete fluid pressure. If a joint should open, even a small amount, a ragged concrete corner will result. When corners are chamfered, this forming operation should be carefully done with precision milled material. If the corner angle is other than 90°, special chamfering material is necessary.

C. Columns require good quality form work, and corners particularly are critical. Columns are often poured rapidly. Unless care is taken, this can result in poor quality concrete work where it is least desirable.

In the design of column forms, the corners should interlock in such a way that each form acts as a spreader when tightening the ties across it. This permits the placement of active compressive stresses in the form units prior to placing the concrete and the possibility of form materials yielding under the fluid concrete pressures sufficiently to open corner joints is minimized. The ties must have wedge or thread action to provide this active encasing force.

Only where rough work can be tolerated should column corners be held by nailing only.

Circular columns are common -- Forms for these utilize ring tension to contain the pressures. Types of forms include:

(1) Single use cardboard tubes which are destroyed in the stripping process.

ADVISORY CIRCULAR

DEPARTMENT OF TRANSPORTATION
FEDERAL AVIATION ADMINISTRATION

SUBJECT: HANDBOOK AND STUDY GUIDE FOR AVIATION MECHANICS INSPECTION AUTHORIZATION

1. PURPOSE. This handbook gives guidance to persons conducting annual and progressive inspections and approving major repairs or alterations of aircraft. It also stresses the important role they have in air safety. While the handbook is primarily intended for mechanics holding or preparing for an Inspection Authorization, it may be useful to aircraft manufacturers and certificated repair stations who have these privileges.

2. CANCELLATION. AC 65.95-2 dated May 3, 1967, is canceled.

3. REFERENCES. Part 65 of the Federal Aviation Regulations sets forth the privileges of mechanics holding an Inspection Authorization. Part 43 of the FARs sets forth maintenance rules and standards of performance.

4. HOW TO GET THIS HANDBOOK.

   a. Order from: Department of Transportation; Federal Aviation Administration; Distribution Unit, TAD-484.3; Washington, D.C. 20590

   b. Identify this publication in your order as: FAA AC No. 65.95-2A Handbook and Study Guide for Aviation Mechanics' Inspection Authorization dated 4/15/69.

   c. This publication will be furnished free of charge.

Director,
Flight Standards Service

2091

Initiated by: FS-340

(2) Multi-use steel plate forms -- these are split into half-cylindrical with bolted joints along each side of the column.

(3) Built up wooden forms are similar to the steel forms but use steel hoops as the pressure resisting element.

D. Horizontal forms used under concrete slabs and girder stems are called soffit forms. They must be designed to carry the full weight of the concrete. Alignment of lower concrete edges requires special attention. Keep the joints tight and provide stiff supporting form members under these locations.

Forms for horizontal spans are usually bowed upward. This is called cambering. Camber is necessary to compensate for the falsework deflection under the load of the concrete. Additional cambering is necessary through the length of the final concrete span to provide for the deflection of the concrete member when the forms and falsework are removed. Mid-span camber should be from 1/600ths to 1/1,000th of the span length.

E. The temporary posts and beams that support horizontal form and concrete loads are called falsework. Uneven settlement in this area can be very serious and complete falsework failure is catastrophic. Falsework plans must be checked for structural adequacy. Falsework is composed of the following units:

(1) Mud-sills or pads supporting falsework must be firmly bedded. If on soil, bed them in fine granular material and protect the soil from softening or scouring by water. Soil bearing pressures under mud-sills are generally limited to about one ton per square foot. Relatively uniform pressures should be developed under adjacent sills so that a final uniform falsework settlement will be obtained.

When adjacent shores rest upon supporting material of completely different yield characteristics, such as, where one shore rests upon a concrete footing and the adjacent shore is supported by a mud-sill on poorly consolidated fill, extreme measures are required to obtain uniform settlement under load. In this case the mud-sill should be extra stiff, it should pass across and be supported on the footing, and its bearing area on the fill should be increased.

(2) Posts, often called shoring, carry the column load in the falsework. They are most often critical in crushing strength where they bear on the sills and caps. The capacity of most falsework timber in cross-grain bearing is about 400 pounds per square inch.

Shoring should be braced with horizontal ribbons in both directions and as often in height as needed to prevent buckling. Diagonal bracing might also be provided in both directions to carry the horizontal or tipping forces.

(3) Cap-beams are important in heavy falsework construction -- they serve to stiffen the frame structure and to distribute uneven settlements and loads. They are sometimes omitted in light construction.

(4) A poor grade of timber should not be used in stringers or joints -- strength and stiffness are important here. On long falsework spans, camber strips are often necessary to compensate for the loaded timber deflection. Block bridging or bracing is required for lateral support of deep stringers.

(5) All falsework must have some means of making elevation adjustments. Wooden wedges are commonly used for this. They must be used in pairs in full bearing and must be firmly nailed in place after making the final adjustment or vibration will loosen them during concrete placement. They are often critical in cross-grain bearing capacity. One of their disadvantages is that they are difficult to back off when releasing the falsework.

Various types of steel screw jacks are coming into more general usage for falsework adjustment. They are very efficient. All of them, however, are somewhat unstable to horizontal forces and lateral bracing should be provided.

(6) Lateral bracing must be provided in falsework to resist horizontal forces. Insufficient lateral bracing is probably the major factor in most falsework failures. The diagonal bracing, mentioned earlier, serves this function. To be effective it must extend from the mud-sills to the deck forms.

(7) There are many patented falsework accessories on the market including variable length stringers and posts. Care must be exercised in their use. Most manufacturers test load samples of their product to failure. Safe working loads are generally assumed at half-failure loads. Untested products should only be used with extreme caution.

6. Form Surface Treatment and Reuse of Forms

Most forms are surface treated to assist in their removal and to preserve them for reuse. Only a form coating material manufactured for this purpose should be used. Care must be used when applying it. It must be kept off concrete construction joint surfaces and reinforcing steel.

The maximum reuse of forms represents a major factor in the economies of modern construction, and it should be encouraged by everyone involved in concrete forming operations.

7. Checking Out Forms

A checking out of the forms is done before concrete placement.

A. The position and alignment is checked from batterboards or construction stakes. Elevations are checked by measuring down from batterboard elevations and up from footings. Dimensions are checked against the contract plans. Imbedded bolts and hardware must be checked out. If these are extensive, a list should be prepared ahead of time.

21155

B. Check for cleanliness. There should be no sawdust nor trash in the forms, and concrete construction joints and reinforcing steel must be clean of oil and mud. Be sure all loose pieces of tie wire and nails are cleaned off the soffit form. If this metal is allowed to remain, it will cause brown rust stains on the exposed concrete surface. Nails temporarily used to support reinforcing steel along wall faces must also be removed.

C. Give special attention to expansion joint details. Be sure these joints are free to move.

8. Forms During Concrete Placement

A. The rate and sequence of concrete placement will be limited by the strength of the concrete forms. As mentioned previously, the pressures due to the fluid head of concrete will limit the depth increase that can be permitted. In well built forms, this is generally 4 to 6 feet per hour.

Horinzontal forms should be uniformly loaded during the placing operations.

Where concrete in a form unit is placed in two operations, such as, where a girder and a slab are poured on different dates, considerable care is required to prevent cracking of the concrete placed during the first pour when the forms deflect further during the loading of the second pour. To prevent this, the first placed concrete should be several days old before making the second pour. This will permit it to attain some strength. In addition, reinforcing steel must be provided where needed to resist tensile stresses set up by form deflection. In girder stems this often requires that special reinforcing steel be placed near the top of the stem pour to resist negative moments which will develop at falsework supports and columns.

B. It is general practice to assign someone to watch forms and falsework while taking the load during the pour. Many failures can be discovered early enough to prevent their becoming serious. Experience has shown that just because a type of form or falsework had been used several times before without problems is no guarantee that it will not fail this time.

To assist this operation, tattle-tale guages are used to check falsework settlement and plumbobs used to check lateral movement.

The form watcher should keep alert for the sounds of spilling concrete and splintering wood. He should watch for deflecting stringers, leaning joists, loosening of braces, and excessive settlement of supports.

9. Stripping and Falsework Release

The method by which forms will be removed should be considered during their construction. Forms in small enclosures particularly require that their method of removal be pre-planned. Sometimes forms in hollow concrete structural units are allowed to remain permanently in place.

If side forms are removed while the concrete is still low in strength, considerable care must be used to prevent damaging the concrete. In this case, too, curing of the concrete must be attended to.

Supporting forms must remain until the concrete has attained sufficient strength for the spans involved. Unusually large deflections can occur in concrete spans where the supporting forms are released too early.

10. Safety

There are inherent hazards during form construction and safety precautions are needed. The personal use of hard hats, stout clothing, and high friction shoe soles are among these.

Published construction safety regulations covering this type of work are available.

CONCRETING DURING HOT WEATHER

Spring and fall usually are considered the ideal seasons for concreting. The temperature extremes that are prevalent in winter and summer are not usually encountered. However, construction proceeds all year. Therefore, concrete must be handled and placed during hot weather. Concreting in hot weather poses some special problems but certainly is practicable provided precautions are observed.

PREVENTING RAPID EVAPORATION

The main precaution during summer concreting is to prevent rapid evaporation of water from the concrete. Consequently, concrete should be protected during and after the placing and finishing operations so that the chemical reaction can proceed unrestricted. Obviously, if too much water evaporates the hydration will not be complete.

Rapid drying sometimes causes problems such as strength reduction and plastic shrinkage cracks. In extreme cases, a rapid loss of moisture from the concrete at the surface may cause cracks to form within the first day or so and often within the first few hours. Concrete may also stiffen before it can be consolidated because of rapid setting of the cement and excessive absorption or evaporation of mixing water. This leads to difficulty in finishing flat surfaces.

TEMPERATURE, RELATIVE HUMIDITY, AND WIND

Several factors affect the rate of evaporation of water from concrete. It is influenced by the concrete and air temperatures, relative humidity, and wind velocity. Even relatively small changes in these conditions may have a pronounced effect on the rate of evaporation, especially if they occur simultaneously.

For example, when the relative humidity changes from 90 to 50 per cent (see Table 19, Part 2), the rate of evaporation is increased five times; if the humidity is further reduced to 10 per cent, evaporation is increased nine times.

When both concrete and air temperatures increase from 50 to 70 deg. F. (Table 19, Part 3), evaporation is doubled; if further increased to 90 deg. F., evaporation is increased four times.

With an air temperature of 40 deg. F., the rate of evaporation is tripled when the concrete temperature is raised from 60 to 80 deg. F. (Table 19, Part 5).

Wind velocity is also important. The rate of evaporation is four times greater when the wind velocity increases from 0 to 10 mph (Table 19, Part 1), and is nine times greater when the wind velocity increases to 25 mph.

21162

It is apparent that the rate of evaporation is highest when the relative humidity is low, when concrete and air temperatures are high, when the concrete temperature is higher than the air temperature, and when the wind is blowing over the concrete surface. The combination of hot, dry weather and high winds often prevailing during summer months removes moisture from the surface faster than it can be replaced by normal bleeding.

CEMENT TEMPERATURE

Cement temperature has only a minor effect on the temperature of freshly mixed concrete. This is due to the low specific heat of cement and the relatively small amount of cement in the mix.

Since the cement loses heat slowly during storage, it may be warm when delivered. This heat is produced during grinding of the cement clinker in manufacture. Since the temperature of cement does affect the temperature of fresh concrete to some extent, some specifications place a limit on its temperature at time of use. However, test results indicate that it is desirable to specify a maximum temperature for freshly mixed concrete rather than place a limit on the temperature of the ingredients.

BEFORE PLACING AND FINISHING CONCRETE

A few simple precautions may save many dollars. These procedures will also give the concrete an earlier strength gain, greater durability, and will greatly reduce chances of surface defects. To assure a quality concrete job, at little or no additional cost, here's what you can do before and after placing and finishing concrete:

Plan ahead. Before beginning extensive concreting operations, check with the weather bureau to obtain latest forecasts for temperature, wind velocity, and relative humidity. (Each, or a combination, influences excessive evaporation of water from concrete. See Table 19.)

Be prepared with necessary equipment and material well in advance of hot weather.

Be sure of an ample water supply for sprinkling subgrades, wood forms, and aggregates, and for curing.

Have tarpaulins or polyethylene sheets and lumber ready for sunshades and windbreaks.

Schedule work so that concrete can be placed with the least delay. Jobs could be started late in the afternoon during extremely hot periods to take advantage of lower evening temperatures and winds.

32	90	90	10	26	10	.336
33	90	90	10	26	25	.740

Use cool materials. If you job mix, keep all materials cool by storing aggregates in shade if possible, sprinkling coarse aggregate with water, and protecting water supply from direct sun rays. Mixing water may be chilled in very hot weather by refrigeration or by using ice as a part of the mixing water. The ice should be melted by the time the concrete leaves the mixer. Most ready mix producers follow these procedures to provide you with cool concrete.

Prevent absorption. Thoroughly moisten subgrade, reinforcing steel, and wood forms just before placing concrete so that they will not absorb water from the mix.

Sprinkling cools the surrounding air and increases its relative humidity. This not only reduces the temperature rise of the concrete but also minimizes evaporation of water during placing. For slabs on ground, it is a good practice to dampen the subgrade the evening before concreting. Prior to placing concrete, there should be no standing water or puddles on the subgrade.

Coarse aggregates should be sprinkled before they are added to the batch.

Fig. 58. Moisten subgrade.

DURING AND AFTER CONCRETE HAS BEEN PLACED

Don't delay placing concrete. Strike it off and darby or bullfloat it at once.

Place temporary covers, such as burlap kept continuously wet, over the fresh concrete immediately after striking and darbying.

When ready for floating and/or final finish, uncover only a small section immediately ahead of the finishers. Cover again at once after final finish and keep the cover wet.

Any delays in finishing air-entrained concrete in hot weather usually lead to the formation of a rubber-like surface which is difficult to finish without leaving ripples or ridges.

Protect against evaporation. When placing concrete under a hot sun and drying winds, make sure the elements do not ruin otherwise top-quality concrete. The problem under such conditions is to prevent rapid loss of water, which may cause plastic shrinkage cracks.

21165

Protect concrete by placing a windbreak on the windward side when high winds prevail. It may also be necessary to fog air over new concrete with a mist of water.

Protect from sunlight. Protect concrete from direct sunlight on hot days by erecting a sunshade or delaying placing operations until late in the day and by taking advantage of the shade from nearby buildings or trees.

Start curing as soon as surfaces are hard enough to resist marring. Cover the concrete with polyethylene film, waterproof paper, or waterholding materials such as straw or burlap, or by spraying on a curing compound. If curing compound is to be used, apply it immediately after final finishing. See that adequate and uniform coverage is obtained.

Fig. 59. Protect concrete.

Keep the concrete surface constantly wet to avoid alternate wetting and drying during the curing period.

Continue curing for at least 3 days and preferably for a week. Water not only acts as a curing agent but also cools the slab.

Fig. 60. Keep concrete surface wet.

21166

RECORDING WEATHER CONDITIONS

Weather conditions should be recorded and made a part of the permanent job record. Humidity, temperature, wind, and clouds should be noted.

TESTING SPECIMENS IN HOT WEATHER

In hot weather it is absolutely necessary that sampling (making and curing test specimens) be done in conformance with standard specifications. ASTM Designation C31, "Standard Method of Making and Curing Concrete Compression and Flexure Test Specimens in the Field," governs the procedure to use for specimens sampled from concrete being used in construction.

Test cylinders definitely should be kept shaded and damp and must be transferred at the age of 1 day to the laboratory (or other suitable location) where they will receive continuous standard moist curing until tested. Damp sand, wet burlap, or fog sprays will ensure retention of water by the specimens.

USE OF ADMIXTURES

Admixtures are sometimes used during hot weather to delay the setting time of concrete and lessen the need for an increase in mixing water. Water-reducing agents may be beneficial provided they do not interfere with strength development and other properties of the concrete and provided their use is carefully controlled. They should be used only to supplement (not replace) other hot weather concreting procedures.

If admixtures are used, they should meet ASTM or federal specifications. They should also be tested with job-site materials under job conditions, including temperature, in advance of construction to determine their compatibility with the other materials and their ability under these conditions to produce the desired properties.

21167

APPLICATION

Lead discussion covering hot weather concreting.

TEST OR DISCUSSION POINTS

1. What seasons are usually considered to be ideal for concreting? Why?
2. What adverse effect does temperature, relative humidity, and wind have on concrete during hot weather?
3. What may happen to concrete in hot weather if precautions are not taken?
4. What planning is necessary before placing and finishing concrete in hot weather?
5. What is meant by "use cool materials"?
6. What can be done to prevent water being absorbed from the mix?
7. What job operations should be completed as soon as possible after concrete is in place?
8. What can be done to protect against evaporation?
9. Is curing necessary during hot weather? Why?
10. How long should concrete be cured during hot weather?
11. What procedures should be followed when securing test specimens during hot weather?

REFERENCE MATERIALS

Refer to ASTM Designation C31, "Standard Method of Making and Curing Concrete Compression and Flexure Test Specimens in the Field."

21168

CONCRETING IN COLD WEATHER

Concrete can be placed throughout the winter months if certain precautions are taken. For successful winter work, adequate protection must be provided when temperatures of 40 deg. F. or lower occur during placing and during the early curing period.

To protect fresh concrete from freezing and maintain minimum permissible curing temperatures, plans should be made well in advance. Appropriate equipment should be at hand and ready to use for heating the concrete materials, for constructing enclosures, and for maintaining favorable temperatures after the concrete is placed. The cost of construction will be increased somewhat by these essential precautions and will vary with the amount of protection required.

EFFECT OF CONCRETE TEMPERATURES

Temperature has a considerable effect on the rate of hardening of concrete and it affects the rate at which hydration of cement occurs. Low temperatures retard concrete hardening and strength gain. Near the freezing point, the rate is very slow and at temperatures below freezing there is almost no increase in strength. At temperatures below 73 deg. F., strengths are lower at early ages but higher at later periods. Concrete made and cured at 55 deg. F. has relatively low strengths for the first few days, but after 28 days it has slightly higher strengths than concrete made and cured at 73 deg. F. Concrete made at 40 deg. F. and cured for 28 days at 25 deg. F. has very little strength at early ages. However, if favorable curing is then provided, this concrete develops strength comparable to that of concrete cured at 73 deg. F.

Strength gain practically stops when moisture required for curing is no longer available. Concrete placed at low temperatures (above freezing) may develop higher strengths than concrete placed at high temperatures. However, curing must continue for a longer period.

HOW TO GET HIGH-EARLY-STRENGTH CONCRETE

There are occasions when it is desirable to increase the setting rate and strength development of concrete. High strength at an early age is frequently desired during winter construction to reduce the length of time protection is required. High early strength may be obtained by using one or a combination of the following:

1. High-early-strength cement
2. Additional portland cement
3. Higher curing temperatures (e.g., steam curing).

21169

The value of using high-early-strength cement during cold weather is often realized through early re-use of forms, savings in the cost of additional heating and protection, and earlier use of the finished concrete.

USE OF CHEMICAL ACCELERATORS

Chemical admixtures known as accelerators are also sometimes used to shorten the setting time and increase early strength development of concrete mixes.

Calcium chloride is the most commonly used accelerating admixture. If used in concrete, it should be added in solution as part of the mixing water. However, the solution should not come into direct contact with the cement or a flash set may occur. If it is added to the mix in dry form, undissolved lumps may cause popouts or dark spots in hardened concrete. In the case of long hauls for ready mix, the addition of the calcium chloride solution is sometimes delayed until after the concrete has been mixed, shortly before discharge. Twenty revolutions of the drum will usually adequately incorporate the calcium chloride thoroughly in the mix.

The American Concrete Institute recommends use of 1 percent calcium chloride by weight of cement for cold weather concreting when mean temperatures are below 40 deg. F. Up to 2 percent by weight of cement is sometimes used. However, calcium chloride in amounts greater than 2 percent can cause problems. It may cause flash set, increase drying shrinkage, and corrode reinforcement. Addition of calcium chloride in recommended amounts has no significant corrosive effect on ordinary steel reinforcement provided the concrete is watertight.

Calcium chloride or admixtures containing soluble chlorides should never be used under the following conditions:

1. In concrete for prestressed concrete construction. Corrosion of the prestressing strands may result.

2. In concrete containing embedded aluminum, such as conduit. Serious corrosion may result, especially if the aluminum is in contact with embedded steel and the concrete is in a humid environment.

3. In lightweight insulating concrete placed over metal decks.

4. In concrete that will be in contact with soils or water containing sulfates.

DON'T DEPEND ON CHEMICALS TO PREVENT FREEZING

After concrete is in place it should be protected against freezing. However, so-called antifreeze compounds or other materials to lower the freezing point of concrete should not be used. The quantity of these materials needed to lower the

21170

freezing point of concrete appreciably is so great that strength and other properties are seriously affected. There is no such thing as an antifreeze for concrete, so don't depend on chemicals to prevent freezing.

Where several cycles of freezing and thawing occur at an early age, strength and other qualities of concrete are permanently affected. However, the strength of concrete that has been subjected to a light freezing at an early age may be restored to normal by resumption of favorable curing conditions. But such concrete will not have the resistance to weathering, nor will it be as watertight, as concrete that has not been frozen.

BEFORE PLACING AND FINISHING CONCRETE

Fig. 61. Plan in advance.

1. Plan in advance. Have equipment and materials ready before cold weather arrives. Provide heaters, insulating materials, and enclosures. Use high-early-strength concrete where job conditions make it desirable.

Fig. 62. Heat the materials.

2. Heat the materials. The temperature of the concrete as it is placed in the forms should be between 50 and 70 deg. F. for slabs. When air temperatures are between 30 and 40 deg. F., the mixing water should be heated. When air temperatures are below 30 deg. F., the mixing water and sand (and sometimes coarse aggregate) should be heated. No frozen aggregate lumps should be in concrete at the time it is placed.

21171

To prevent flash set, materials should not be overheated. Maximum allowable water temperature is about 140 deg. F.

Do not place concrete on frozen ground--unequal settling will occur when the ground thaws. This can cause cracking.

Fresh excavations should be covered with straw or other insulating material to prevent the ground from freezing until concrete can be placed.

Remove all ice and frost from forms and steel reinforcing.

3. Use accelerators carefully. Use about 1 lb. of calcium chloride per bag of cement to hasten hardening. Not more than 2 lb. should ever be used because of danger of flash set.

Don't use any admixtures to prevent concrete from freezing.

Don't use calcium chloride with other admixtures which accelerate hardening.

Fig. 63. Provide suitable curing temperatures.

AFTER CONCRETE HAS BEEN PLACED

1. Provide suitable curing temperatures. Maintain the temperature of the concrete, when using normal portland cement, at 70 deg. F. or above for 3 days, or 50 deg. F. or above for 5 days.

Maintain the temperature of high-early-strength concrete at 70 deg. F. or above for 2 days, or 50 deg. F. or above for 3 days.

Do not allow the concrete to freeze during next 4 days.

Cool the concrete gradually at a rate of 1 to 2 deg. per hour until it reaches the outside temperature.

2. Keep job condition records. Record date, hours, weather conditions, and temperature (both of air surrounding concrete and surface of concrete) at least twice daily.

Fig. 64. Keep job condition records.

21172

3. Protect concrete. Insulation, such as a thick blanket of straw, without artificial heat, is often sufficient protection for slabs on ground. At lower temperatures, housing and artificial heat are necessary.

Housings can be made of wood, insulation board, waterproof paper, or tarpaulins over wood frames.

Circulate moist warm air between floor slabs and housing.

Avoid the risk of fire by placing coke or oil-fired heating units away from flammable material. Vent to outside.

Raise heating units above the floor to avoid rapid drying of concrete underneath.

Keep concrete moist, especially near heating units. In cold weather, when artificial heat is applied, moisture for curing is still very important. First wet the slab well with water and cover with waterproof paper. Then apply heat to keep from freezing. This water treatment, along with covering, prevents the surface of the slab from drying out.

Fig. 65. Protect concrete.

CURING METHODS

Concrete in forms or covered with insulation seldom loses enough moisture at 40 to 55 deg. F. to impair curing. However, moist curing is needed during winter concreting to offset the drying tendency when heated enclosures are used. It is important that concrete be supplied with enough moisture when warm air is used to maintain favorable temperatures.

Live steam exhausted in an enclosure is an excellent method of curing because it provides both heat and moisture. Steam is especially practical during extremely cold weather because moisture provided by steam offsets the rapid drying that occurs when very cold air is heated.

Early curing with liquid membrane-forming compounds may be used on concrete surfaces within heated enclosures. It is a better practice, however, to cure first with water or exhaust steam during the initial period of protection and then apply a curing compound after the protection is removed and the air temperature is above freezing.

21173

31 OF 327

ED

056 238

MICROCOPY RESOLUTION TEST CHART

NATIONAL BUREAU OF STANDARDS-1963-A

Heat may be retained in the concrete by use of commercial insulating blankets or bat insulation. The effectiveness of insulation can be determined by placing a thermometer under the insulation in contact with the concrete. If the temperature falls below the minimum required, additional insulating material should be applied. Corners and edges of concrete are most vulnerable to freezing and should be checked to determine the effectiveness of the protection.

Recommendations on the amount of insulation necessary for protection of concrete at various temperatures may be obtained from the manufacturers of these materials or by referring to the American Concrete Institute's "Recommended Practice for Winter Concreting" (ACI 604).

Heated enclosures are commonly used for protecting concrete when air temperatures are near or below freezing. There are a number of suitable materials for making enclosures.

Enclosures may be heated by live steam, steam in pipes, oil-fired burners, salamanders, and other heaters of various types. Salamanders are easily handled and inexpensive to operate. They are convenient for small jobs but have several disadvantages. They produce a dry heat, so care must be taken to prevent drying of the concrete, especially near the heating element. When placed on floor slabs, they should be elevated and the concrete near them protected with damp sand.

Salamanders and other fuel-burning heaters also produce carbon dioxide, which combines with calcium hydroxide in fresh concrete to form a weak layer of calcium carbonate. When this occurs, the surface of a concrete floor will dust under traffic. For this reason, carbon dioxide-producing heaters should not be used while placing concrete and for the first 24 to 36 hours of the curing period unless they are properly vented.

REMOVE FORMS AT PROPER TIME

During cold weather, allow ample time for concrete to attain its required strength before removing forms. Removing forms too soon may cause the corners and edges to chip. Let forms remain in place until the concrete has attained sufficient strength to sustain its own weight in addition to any other load that may be placed upon it during construction.

APPLICATION

Discuss cold-weather concreting methods.
Show slide 11 from Mr. Quality Concrete slide set.

TEST OR DISCUSSION POINTS

1. Can cold weather concreting be accomplished without damaging the properties of concrete?
2. What is the effect of temperature on the rate of hardening?
3. At what temperature should provisions be made for adequate protection during cold weather concreting?
4. Explain three methods for obtaining high-early-strength concrete.
5. Why should one be careful when using chemical accelerators?
6. What is the maximum recommended amount of calcium chloride, by weight of cement, that should be used in concrete?
7. Under what conditions should calcium chloride or soluble chloride never be used?
8. Is there such a thing as an antifreeze for concrete? Why?
9. Name several things that should be done before placing and finishing concrete in cold weather.
10. Name several things to do after placing concrete in cold weather.
11. How long should the temperature of concrete be maintained at 70 deg. F.? At 50 deg. F.?
12. What cold weather curing methods are suitable for your area?
13. What precautions are necessary when using salamanders?
14. What may happen to concrete if forms are removed too early?
15. How long should forms remain in place?

TOOLS AND MATERIALS

JOINTS FOR FLAT CONCRETE WORK

Three basic types of joints are commonly used in slab-on-ground construction--isolation, control, and construction joints. They are easy to put in and should be used in flat work such as floors, slabs, and walks.

WHY JOINTS ARE NECESSARY

All plastic concrete contains more water than is needed for hydration of the cement. When this extra water starts to evaporate, drying-shrinkage of the slab begins creating tensile stresses in the concrete. These tensile stresses must be relieved by providing joints; otherwise unsightly cracks will develop.

Slabs of varying shapes and sizes expand and shrink by different amounts. The larger the slab, the greater will be the horizontal movement. Provision must be made for this differential movement to prevent unnecessary cracking.

Slabs may also have some vertical movement due to heaving or settling of the subgrade. The amount of movement may vary due to lack of uniform subgrade bearing pressures, unequal loading conditions, changes in moisture content of the soil, and freezing and thawing of the subgrade.

Slabs may also require joints that are not concerned with movement, but rather with ease of concrete placement. Many times this type is combined with another type of joint.

ISOLATION JOINTS FOR POINTS OF ABUTMENT

Isolation joints are used to separate slabs-on-ground from points of abutment such as walls, columns, and footings. By separating or isolating the slab, it is permitted to move without unsightly cracks developing.

To prevent bonding and provide a cushion, a continuous rigid asphalt-impregnated insulation strip, building paper, polyethylene, or similar material is placed upright between the edge of the slab and the immovable object. The joint material need not be more than 1/4 in. thick.

If watertight joints are desired, they can be formed with beveled wood siding or strips held from the wall by wedges. The wedges and strips can be easily removed after the concrete has hardened, and the space is partially filled with sand and other resilient material to provide a watertight joint.

CONTROL JOINTS TO PREDETERMINE CRACK LOCATIONS

Concrete has a tendency to contract or shrink in cooler temperatures or when it loses moisture. In large slabs of concrete this shrinkage, if uncontrolled,

21176

will cause random cracking at 15- to 25-ft. intervals, depending upon such factors as (1) total amount of water in the concrete mix; (2) temperature and humidity ranges experienced; and (3) subbase restraint. Therefore, it's best to predetermine the crack location. This is done by cutting into the slab to create a series of weakened planes. The weakened planes or joint spacing should be laid out so that slab panels are approximately square. Slabs that are not rectangular or square should have a control joint across the slab at the point of juncture of the offset. Control joints are generally placed 10 to 15 ft. apart on floor slabs, driveways, and livestock feeding floors. They are placed 4 to 5 ft. apart on sidewalks. Cracks will follow the grooves or joints and random cracking is prevented.

Control joints are cut to a depth of 1/4 to 1/5 the thickness of the slab. Depth is important. If the cut is too shallow, the crack forms elsewhere. If the cut is too deep or all the way through the slab, load transfer may not be obtained. This would result in a differential vertical movement. With properly cut joints, aggregate interlock prevents unequal settlement of the slabs. Cuts should be made as soon as possible after placement of the concrete in order to work larger pieces of aggregate away from the joint. A simple way to cut this type of joint is to use a groover or jointer with a bit 3/4 to 1 in. deep. Another method of providing a joint is to use a brick mason's trowel to cut the concrete. A groover is then used to finish the joint.

Another method of cutting joints is with an electric or gasoline-powered saw. The joint is usually cut in the concrete surface 4 to 12 hours after the concrete has hardened or as soon as the concrete surface will not be torn or damaged by the saw blade kerf.

CONSTRUCTION JOINTS FOR PLACING LARGE AREAS IN STAGES

A true construction joint should constitute neither a plane of weakness nor an interruption in the mass of concrete. Therefore, every effort must be made to ensure bonding of the newly placed concrete to that previously placed. To assure bond, the old concrete should be thoroughly cleaned and dampened before the new concrete is put in place. To avoid the possibility of breaking the bond after the pavement is in use, tiebars or keyways are frequently used to assist in vertical transfer across the joint. Tiebars have the added advantage of being able to resist shearing stresses caused by differential shrinkage of the "old" and "new" concrete.

COMBINATION CONTROL AND CONSTRUCTION JOINTS

A method is available for forming a control joint along with a "semi-construction" joint. Instead of creating a weakened plane, the joint is constructed completely through the slab. The resulting joint is a non-bonded and keyed control joint as shown in Fig. 50. Bond is broken between the new and previously placed slabs by spraying or painting with a curing compound, asphaltic emulsion, or form oil, which allows freedom of horizontal movement necessary for crack control. The key provides the same type of vertical load transfer achieved by the aggregate interlock in the cut joints and prevents unequal settlement of the slabs.

21177

Notes: A beveled 1 x2'' strip is adequate for most slabs

Saw kerf prevents breaking up concrete edge when moisture expands 1 x2''

(Used when necessary to stop and join later)

Keys of galvanized metal may be used.

Fig. 50. Combination control and construction joints.

Keyways may be formed by a sheet metal form, premolded mastic 1/8 in. thick, composition hardboard, or 2-in. lumber with a metal strap or wood strip attached to form the groove. If wood strips are used to form the keyway, they may swell when absorbing moisture from the concrete and cause cracking of the concrete lip above the keyway. Therefore, they should be well oiled and grooved with a saw kerf to minimize swelling. A 1x2-in. keyway with beveled edges is sufficient for slabs of 5- to 8-in. thickness. Larger keyways, such as 2x2-in., should be avoided. If metal is used to form the keyway, it should be thick enough to withstand handling. One advantage of the metal keyway form is ease of cleaning for re-use.

APPLICATION

Discuss joints for flat concrete work.
Show Slides 34 through 39, Mr. Quality Concrete slide set.

TEST OR DISCUSSION POINTS

1. Explain why joints are necessary for flat concrete work.
2. Where is an isolation joint used?
3. How is an isolation joint formed?
4. Why is it used?
5. Explain how to obtain a watertight joint.
6. Why are control joints required?
7. What should be the spacing for control joints?
8. How deep should they be cut?
9. What occurs if the joint is too shallow? Too deep?
10. Explain the procedure for making control joints.
11. What is a construction joint and when should it be used?
12. Where would a combination control-construction joint be used?
13. When a wood strip is used to form the groove for a keyway, what precaution should be observed?
14. What size strip is adequate for 5- to 8-in. slabs?

TOOLS AND MATERIALS

Mr. Quality Concrete slide set

CONCRETE TROUBLESHOOTING

Concrete made with good materials, properly proportioned, thoroughly mixed, with optimum air entrainment, and, properly placed, finished and cured will be quality concrete. Concrete made in accordance with the principles outlined in this text will perform well.

However, since rules can be, and often are broken, difficulties do occur and remedies must be found.

To assist in determining the causes of, and correcting some of the more common problems that do occur, the following list of difficulties, their causes, and some of their preventive measures is presented.

Low Cylinder Strength

Cylinders are not meeting specified strengths. Section 504 of the 1963 ACI code requires the following:

1. For structures designed in accordance with Working Strength Design methods, the average of any five consecutive strength tests of the laboratory-cured specimens for each class of concrete shall be equal to or greater than the specified strength, and not more than 20 percent of the strength tests shall have values less than the specified strength.

2. For structures designed in accordance with Ultimate Strength Design methods, and for prestressed structures, the average of any three consecutive tests of the laboratory-cured specimens for each class of concrete shall be equal to or greater than the specified strength, and not more than 10 percent of the strength tests shall have values less than the specified strength.

Causes	Preventive Measures
1. Improper mix design	Increase cement content, decrease water/cement ratio, check aggregate grading and proportions.
2. Proper mix design, but inadequate cement content	Check scales, hoppers and chutes to assure cement is being supplied to the mixer as specified.
3. Proper mix design, adequate cement content, but excessive water added at batch plant or job site	This is the major universal cause of low strength concrete. Slump should be maintained within specified limits. If water needed, also add cement and mix thoroughly.
4. Proper mix design, but variations in consistency caused by: a. Poor control of water content b. Excessive variation of moisture in aggregate c. Non-uniform materials and grading d. Variations in proportions	Improve batching and testing procedures.

Low Cylinder Strength-Continued

Causes	Preventive Measures
5. Air-entrained concrete supplied when not specified	When air-entrained concrete is to be used, the mix must be redesigned to compensate, with some reduction in water and sand content, and perhaps some adjustment of cement content (depending on richness of mix).
6. Cylinders improperly made	Samples from which compression test specimens are to be made shall conform to "Method of Sampling Fresh Concrete"-- ASTM C 172. Specimens to check proportions, or as a basis for acceptance shall conform to "Method of Making and Curing Concrete Compression and Flexure Test Specimens in the Field" -- ASTM C 31. Strength tests shall be made in accordance with "Method of Test for Compressive Strength of Molded Concrete Cylinders" -- ASTM C 39.
7. Impurities in water and aggregates	Organic materials from swamp waters, sewage, sulfates, humus, as well as trucks which have carried sugar, fertilizers, stock feed, etc., will seriously reduce strength. Check water and aggregates for these impurities. ASTM C 40
8. Incompatible admixtures	Check compatibility of admixtures with the concrete ingredients and with other admixtures by mixing batches without the admixtures.
9. Excessive fines in the mix	Reduce sand content if oversanded. If aggregates are degrading from mixing too long, reduce mixing time. Wash dirty sands and coarse aggregates. Check abrasion resistance of aggregates by ASTM C 131.

Poor Finishability

Finishability can only be judged by the concrete finisher. Slump is not an indication of finishability, although some factors affecting slump also affect finishing characteristics.

Causes	Preventive Measures
1. Insufficient sand	Increase sand content, and/or, use air-entraining agent.
2. Poorly graded sand	Correct gradation. Add fines if needed, especially those sizes passing a #50 sieve.
3. Harsh aggregates	Increase sand content, insure proper grading. Use air-entraining agent.
4. Sliver-shaped aggregates	Screen, if possible. Seek other source of aggregates.
5. Insufficient cement	Increase cement content of mix. May greatly aid finishing.
6. Improper mix design	Check mix design.
7. Improper finishing sequence, tools and/or timing	Suggested finishing sequence: Sidewalks, Driveways, etc.:

Placing: Consolidation
Strike off
Darby or Bullfloat
(LAPSE OF TIME)
Edging
Jointing (Grooving)
Finishing: Floating*
Troweling**
(LAPSE OF TIME)
Texturing (Broom, Burlap)
Curing

* Non-air-entrained, wood float
Air-entrained, aluminum or magnesium float.
**Troweling may be omitted if float finish desired.

Floors, etc.:
Placing: Consolidation
Strike off
Darby or Bullfloat
(LAPSE OF TIME)

21182

Poor Finishability-Continued

Causes	Preventive Measures
	Edging Jointing (Grooving) Floating* Finishing: Troweling* (LAPSE OF TIME) Second Troweling* Final Troweling (Hand) Curing *Power or hand troweling LAPSE OF TIME in some cases may be several hours.
8. Lightweight aggregate of non-uniform moisture condition, or replacement of light weight fines with normal weight fines may produce finishing difficulties	Follow manufacturers' recommendations when using light weight aggregates.
9. High air contents in excess of recommended contents, especially in hot weather, cause a sticky surface	Use an air meter to control air content.

Poor Workability

The ease or difficulty of placing and consolidating concrete is called workability. Consistency is measured by means of a slump test, and is not necessarily a measure of workability.

Causes	Preventive Measures
1. Insufficient sand	Increase sand content, and/or, use air-entraining agent.
2. Poorly graded sand	Correct gradation. Add fines if necessary.
3. Insufficient cement	Increase cement content.
4. Improper mix design	Check mix design and correct.
5. Prolonged mixing, raises temperature, reduces slump, may increase fines with soft aggregates	Follow manufacturer's recommended mixing speeds. Do not exceed maximum mixing specifications. ASTM C 94, "Standard Specifications for Ready-Mixed Concrete" provides mixing information.

21183

CHAPTER 1. ISSUANCE, RENEWAL, AND CHANGE OF FIXED BASE

1. ISSUANCE. Section 65.91 of the FAR sets forth the issuance rules for an Inspection Authorization.

   a. Apply for the Inspection Authorization at the nearest FAA General Aviation District Office. Applicants outside the United States should apply to the International Field Office. Tests are given by appointment only and usually take a minimum of five hours.

   b. The applicant is required to provide all the reference material needed for the test. A list of the publications needed and where to obtain them is given in Appendix 1 of this handbook.

   c. Applicants who are employed full time in aviation maintenance under the Federal Aviation Regulations will be considered to have been actively engaged. Those working part time should be evaluated by the Inspector to whom they apply.

   d. An AI needs a fixed base where he can be contacted for FAA administrative purposes. A list of AIs and their locations is made available for people who might need an AI's services.

   e. The AI needs equipment, facilities, and data to help him do a good job. Our modern, complex aircraft require maintenance to be done "by the book" and the use of special tools or equipment to do the work accurately and efficiently.

   f. The written test is designed to test your ability to inspect an aircraft, and how to approve major repairs and alterations. You should know how to use reference indexes to be able to locate specific information quickly:

      (1) Part 1 of the test consists of 10 questions and has a time limit of 20 minutes. It is based on the issuance, privileges, and limitations of the Inspection Authorization. Use of reference material is not permitted during this part of the test.

      (2) Parts 2 and 3 consist of 20 questions each and have a time limit of two hours for each part. They cover situations you would likely encounter while doing annual and progressive inspections and approving major repairs and alterations. Some questions relate to a specific aircraft that is assigned by the test monitor. You will be expected to use or be familiar with the following:

         (a) FARs pertaining to maintenance and airworthiness certification.

         (b) Specifications: Aircraft, engine, and propeller.

         (c) Type certificate data sheets.

Retarded Set

Concrete does not harden or gain strength at a normal rate.

Causes	Preventive Measures
1. Organic impurities in concrete	Organic materials from swamp waters, sewage, sulfates, as well as trucks which have carried sugar, fertilizers, stock feed, etc., will seriously reduce strength and retard set.
2. Improper use of water-reducing and/or retarding admixtures	Use in accordance with manufacturers' recommendations.
3. Concrete too cold	In cold weather, heat concrete, protect concrete in place from cooling.

Rapid Stiffening

Concrete stiffens rapidly becoming difficult to finish.

Causes	Preventive Measures
1. Concrete too warm	Aggregate stockpiles should be kept wet to cool by evaporation. May be necessary to cool mixing water with ice.
2. Concrete mixed too long	Follow recommended mixing times. Counters on trucks.
3. Concrete in truck too long	Follow recommended time in transit, ASTM C 94. Time of charging mixer should be recorded.
4. Aggregates dry (Primarily in old stockpiles)	Aggregates should be kept damp in the stockpile, so that they will not absorb water from the mix.
5. Subgrade dry	The subgrade will draw moisture from the fresh concrete unless it has been previously dampened. On some highly absorptive subgrades, wetting may require a day in advance of placing concrete.

Scaling, D-Cracking

Scaling may be occurring when the surface of a hardened concrete slab tends to crumble and break away from the slab. D-Cracking is a form of distress in concrete surfaces characterized by the successive formation of a series of fine cracks at rather close intervals, often of random patterns, but in slabs paralleling the edges, joints and cracks and usually curving across slab corners. Both of the above may occur in areas subjected to frequent freezing and thawing.

Causes	Preventive Measures
1. Cycles of freezing and thawing when non air-entrained concrete was used.	Use adequate amount of cement and air-entrainment.
2. Early cycles of freezing and thawing of the surface of newly placed air-entrained concrete	The temperature of freshly placed concrete should be maintained above 50 degrees F. for at least five days when using normal portland cement, and 50 degrees F. for at least three days when using high early strength cement. Thirty days of drying should occur after curing is completed, prior to the application of ice control chemicals.
3. Faulty workmanship. Any one of the finishing operations -- screeding, darbying, floating or troweling -- performed while free water or bleed water is on the surface, will create a condition in the top surface layer conducive to scaling, even when the concrete is properly air-entrained.	No finishing operation should ever be performed while free water is present on the surface.

Frozen Concrete

Surface of concrete crumbles after exposure to below-freezing weather while still in the plastic state, or before adequate strength has been attained.

Causes	Preventive Measures
1. Concrete frozen while in the plastic or weak state, generally from the surface inward	In cold weather, heat concrete. Protect new concrete from freezing by use of insulation and heaters. Do not place concrete on frozen ground. See course unit on "Concreting in Cold Weather."

21185

Spalling

Spalling is the disruption of otherwise sound concrete by force, generally taking the form of chipping or shattering in the vicinity of joints or cracks, or over rusting reinforcement or expanding aggregate.

Causes	Preventive Measures
1. Severe loading, especially on an exposed corner	Do not overload concrete. Avoid point loadings.
2. Rusting reinforcing bar	Protect reinforcing with adequate cover of concrete over the bars.
3. Restraint which prevents normal movement of a slab or other concrete member. Movement would be caused by variations in temperature and moisture.	Arrange joints in such a manner that concrete members will not be restrained and can freely adjust themselves to size variations.
4. Foreign material in a joint	Keep joints clean.

Blister

Bubbles form in the surface of the plastic concrete during finishing operation.

Causes	Preventive Measures
1. Improper finishing tools and techniques	Use a wood float after strikeoff.
2. Excessive slump, especially in hot weather	Use concrete with slump less than four inches.
3. Extreme difference of temperature between concrete and surface on which concrete is being placed	Concrete temperature should be within 10 degrees of surface on which it is to be placed.
4. Poor gradation of sand	Check sand grading and correct.
5. Excessive air content	Check air content and correct.
6. Improper use of retarders	Follow manufacturers' directions.

Discoloration

Light and dark areas and markings on the surface of the concrete, particularly with troweled surfaces.

Causes	Preventive Measures
1. Sprinkling dry cement on the surface of the concrete during finishing. May also lead to scaling and alligator cracking	Dry cement should never be sprinkled on the surface of the concrete.
2. Use of a metal trowel for final troweling of a concrete surface which contains chlorides and which has not been cured	Cure concrete. Wet curing or covering recommended.
3. Mixes containing impurities	Be sure materials are clean.
4. Use of various tyeps of coverings for curing	Curing should be applied evenly. Blankets and membranes should be securely anchored in place.

Abrasion

Excessive wear of the concrete, exposing the aggregates.

Causes	Preventive Measures
1. Inadequate concrete strength	Increase cement content, decrease W/C ratio. Follow principles for making high strength concrete.
2. Lack of curing	Concrete must be cured under favorable conditions of temperature and moisture. There is no such thing as "dry curing". "Dry curing" is no curing.
3. Soft aggregates	Use abrasion-resistant aggregates. See ASTM C 131, "Abrasion of Coarse Aggregates by use of Los Angeles Machine."
4. Other	See "Dusting."

Popouts

Round conical pits 1/4" or deeper in the surface of outside concrete slabs, varying in size with the depth and size of the aggregate particle and the strength of the concrete surface.

21187

Causes	Preventive Measures
1. Certain types of aggregate particles, such as coal, clay, lignin, flint, glass, etc. Such aggregates swell in the presence of moisture and freezing, or by a chemical reaction between the alkalis in the cement and alkali-reactive aggregates. Sufficient pressure is often built up around the offending aggregate particle to force concrete to break away from it near the surface. This condition is aggravated by freezing and thawing.	Often, popouts are more objectionable from the standpoint of appearance than from danger to structural integrity. If popouts are objectionable, aggregates which have a history of producing popouts should be beneficiated or rejected. A tamper may be used to push aggregates down, provided it is not used to excess. Such aggregate should be pushed down about one inch from the surface. A two course slab with known satisfactory aggregate in the top course may also be employed.

Dusting

Dusting is the appearance of a powdery material at the surface of a hardened concrete slab.

Causes	Preventive Measures
1. An excess of clay or silt in the concrete	Use clean, well-graded coarse and fine aggregate.
2. Premature floating and troweling	Delay floating and troweling until all free water or excess moisture has disappeared and concrete has started its initial set. See proper finishing sequence.
3. Carbon dioxide from open salamanders or power buggy and mixer engines	Vent combustion fumes to the outside. Provide sufficient ventilation.
4. Condensation on the surface before floating and troweling operations have been completed	Provide adequate ventilation and air circulation in enclosed areas.
5. Concentration of dry heat from heaters on freshly placed concrete may inhibit proper hydration of cement	Water jackets may be needed on heaters to increase humidity. Location of heaters may be changed periodically.
6. No curing or inadequate curing	Proper curing for the specified length of time is essential. Concrete that is not cured will often be weak and the surface easily worn by foot traffic.
7. Excessive slump	Use recommended slump.

Volume Change Cracking

Like other construction materials, concrete expands and contracts under various conditions of moisture and temperature. When provision is not made for these volume changes, uncontrolled cracks will result. Generally these cracks do not materially reduce the structural capacity of the concrete, but they may be unsightly.

Causes	Preventive Measure
1. Lack of or inadequate control joints in slabs and walls	Follow recommended jointing procedures. Floors, mzximum joint spacing - 20 feet. Outside flatwork, maximum joint spacing - 15 feet. Walls, maximum joint spacing - not more than 25 feet. Local experience may dictate joint spacings different than the above, since joint spacing necessary to control cracking is related to water content and other characteristics of the concrete.

Structural Cracking

A crack through a slab on grade which has been properly jointed, generally across a corner or parallel to an edge.

Causes	Preventive Measures
1. Inadequate design thickness	Proper design
2. Too early loading	Assure adequate concrete strength before allowing the slab to be loaded.
3. Excessive loads, greater than design loads	Avoid overloads.
4. Poor support	Adequate and uniform compaction of foundation materials. Remove all vegetation, loose earth, mud and organic materials from the sub-grade. Remove all soggy or soft spots, replace with dry earth, cinders, slag or gravel, compacted. A well compacted foundation of 4" to 6" depth is recommended. Where an area is to be filled before concrete is placed, fill material should be placed in layers not exceeding 4 - 6" and each layer thoroughly compacted.

Construction Caused Cracks

Cracks caused by some difficulty occuring during construction.

21189

Causes	Preventive Measures
1. Construction loads in excess of design loads	Avoid overloading.
2. Settlement of shoring and forms	Assure adequate form support and bracing. See unit on forms.

Plastic Shrinkage Cracks

Plastic shrinkage cracks are random cracks that sometimes occur in the exposed surface of fresh concrete while the concrete is still plastic and before attaining significant strength. They are primarily unsightly, but do not impair the performance of a slab or structure.

Causes	Preventive Measures
1. Excessively rapid evaporation of water from the surface of the concrete	The early application of appropriate curing procedures is the most effective means for preventing plastic shrinkage cracks. Reduce the rate of evaporation by erection of windscreens and sunshades. Use a fog spray in the air over the concrete, but do not sprinkle the concrete. Dampen the subgrade and forms. Dampen the aggregates if they are dry and absorptive. Lower the temperature of the concrete in hot weather if necessary. Avoid overheating the concrete in cold weather. Reduce time between placing and finishing to a minimum. Apply curing as soon as possible after final finishing. Protect the concrete with temporary coverings.

Crazing

Crazing is the occurence of numerous fine hair cracks in the surface of a newly hardened slab due to surface shrinkage. These cracks form an overall pattern similar to a crushed eggshell.

Causes	Preventive Measures
1. Rapid surface drying usually caused by either high air temperatures, hot sun, or drying winds, or a combination of these	Apply fog spray or cover with burlap or canvas immediately after screeding and darbying. Keep covered until ready for floating and troweling. Cure as soon as possible without marring the surface. See Plastic Shrinkage Cracks.

21190

Causes	Preventive Measures
2. Premature floating and troweling	Do not start floating and troweling until excess moisture has evaporated from the surface.
3. Overuse of the jibberbug, vibrating screed, darby or bull float may contribute by working an excess of mortar to the surface	Use these tools properly.

Honeycomb

Open areas and holes in formed concrete.

Causes	Preventive Measures
1. Use of a harsh, dry mix not properly consolidated. This is sometimes due to excessive or prolonged mixing during hot weather often because of poor scheduling of trucks.	Redesign mix to provide better workability. Use proper consolidation methods. The entire layer or lift of concrete should be vibrated. Vibrators should be inserted rapidly and withdrawn slowly, just the reverse of what appears to be normal practice. Concrete along forms should be spaded, or puddled. Forms may be vibrated or tapped.
2. Loss of cement or mortar through cracks or knot holes in the forms, sometimes called rock pockets or gravel streaks.	The use of good quality, tightly built forms. See unit on Forms.

Sand Streaking

Sand streaking shows as areas of sand giving a non-uniform appearance to formed concrete.

Causes	Preventive Measures
1. Oversanded mix	Redesign mix.
2. Improper vibration	Vibrate properly. See unit on Placing Concrete.
3. Wet mix	Use stiffer mix. Air-entrainment will greatly reduce sand streaking.
4. Improper placement	Use a drop chute to avoid bouncing concrete against forms and rebars during placing. Lifts should not 18 to 24 inches when appearance important.

21191

Flow Lines

Concrete layers show in formed concrete.

Causes	Preventive Measures
1. Concrete placed in piles in forms instead of even layers	Concrete should be placed in even lifts generally not exceeding 18-24 inches throughout the forms to avoid layers of concrete flowing over other concrete.
2. Improper vibration	Vibrators should extend through the lift to the previously placed lift and withdrawn properly.

Application

Discuss the Causes and Preventive Measures of the common difficulties.

Test or Discussion Points

1. Explain the causes of and preventive measures for each of the 21 difficulties listed in the text.

2. Define quality concrete.

Tools and Materials

Photographs of difficulties, specimens, sample laboratory reports.

Reference Materials

1. Portland Cement Association, Finishing Concrete Surfaces -- Preventing Blemishes, CP83.

2. Permanente Cement Company, Concrete Surface Defects -- Causes, Prevention and Repair, Technical Service Dept. Bulletin No. 17.

(d) Procedures for conducting annual and progressive inspections.

(e) Rules pertaining to the Inspection Authorization; issuance, privileges, and limitations.

(f) Airworthiness Directives.

2. RENEWAL. All Inspection Authorizations expire on March 31 of each year. For renewal you should be prepared to show that you have had the activity required in FAR 65.93.

a. Renewals usually are done in conjunction with a safety meeting designed to help the AI with his work. These usually include:

(1) Discussion of maintenance problems of a general nature.

(2) Discussion of recent regulation changes and how they affect the AI.

(3) When available, manufacturers of aviation products hold service clinics, etc., to acquaint an AI with current or new equipment and service problems.

b. If you are unable to attend these meeting or if none is held in your area you should arrange with your local FAA office for renewal during the month of March.

3. CHANGE OF FIXED BASE. Change of address of a fixed base of operations by an AI requires that the FAA be given written notice prior to exercising his privileges at the new address.

FILM LIST

Several 16 mm. sound-color motion pictures produced by the Portland Cement Association are available to you and your group on a free loan basis.

Instructional films are effective teaching aids. Good films enable an instructor to make a presentation that is understood more easily than written or spoken words.

Here is a list of films now available. Instructions on how to order appear at the end of the list.

Building a Highway (15-1/2 minutes). Use in Unit 3. This film shows the construction of a modern highway from the initial planning stages through the final ribbon-cutting ceremony. It explains in layman's language the complicated work of planning, designing, and engineering for today's heavy-traffic roads. Some unusual and colorful animation shows construction of the Appian Way in ancient Rome, development of other ancient roads, and the history of highways in the United States.

Building the Acacia Avenue Reservoir (14 minutes). Use in Unit 3. This is an on-the-job report of the construction of a 4-million-gallon buried reservoir constructed with ready mixed concrete and precast roof elements. The film explains the need for such reservoirs and points out interesting construction procedures. It was produced with the cooperation of the City of Fullerton, Calif.

Concrete Example (16 minutes). Use in Unit 11. Particularly recommended for agricultural students. This film shows how to obtain good concrete jobs with the materials and equipment available. It includes directions for selecting aggregates and for mixing, placing, finishing, and curing concrete. A recommended method of ordering and using ready mixed concrete is also covered.

Concrete in the Sixties (approx. 22-1/2 minutes). Use in Unit 1. An annual newsreel of outstanding and exciting concrete projects in North America. The film shows new applications of concrete in the United States and Canada.

Concrete-Lined Irrigation Canals Save Water (15 minutes). Use in Unit 21. This film dramatizes the importance of concrete canal linings in conserving irrigation water. In addition basic steps in the construction of lined canal systems are discussed and illustrated.

Construction of a Demonstration Section of Prestressed Concrete Pavement (10 minutes). Use in Unit 18. The film shows all steps in construction of a 1,500-ft. section of 9-in.-thick prestressed concrete taxiway at Biggs Air Force Base in Texas. Scenes include tearing up the old pavement, preparing subbase and subgrade, locating ducts for prestressing strands, and methods of stressing longitudinal and transverse strands. Produced in cooperation with the U.S. Air Force and the U.S. Army Corps of Engineers, the movie was filmed during conversion of Biggs AFB facilities for full jet operations.

From Mountains to Microns (24-1/2 minutes). Use in Unit 4. This film shows production of portland cement from raw materials to the finished product. It includes outstanding examples of concrete construction, the use of cement in making concrete, and a brief examination of the organization and work of the Portland Cement Association.

How to Make Decorative Patio Floors for Outdoor Living (19-1/2 minutes). Use in Unit 14. The film shows all the required steps in producing decorative patio slabs with exposed aggregate and colored finishes. Flagstone, incised geometric, and leaf patterns are illustrated.

How to Transport, Place, Finish, and Cure Quality Concrete (32 minutes). Use in Units 13, 14, or 15. It follows the steps involved in taking a proper concrete mix from the mixer by means of buggies, buckets, chutes, trucks and pipes to the point of placement. The film shows approved methods for placing concrete in horizontal and vertical forms, proper finishing techniques for slabs and for vertical walls, and a variety of curing methods with particular emphasis on winter protection.

New Shapes in Concrete (16-1/2 minutes). Use in Unit 3. This film provides an exciting look at the large number and variety of shell structures--domes, barrels, folded plates, and hyperbolic paraboloids--that have been erected all over America. A section of the film demonstrates the principles of shell construction and a portion is devoted to the brief but astounding history of shell design and construction in Europe and the Western Hemisphere.

Pageant of American Farms (16 minutes). Use in Unit 1. This film traces the history of agriculture from the days of the rugged, self-sufficient pioneer to modern push-button farming. It shows authentic old-time equipment and early farming methods contrasted with the latest innovations such as confinement feeding systems of livestock breeding and feeding. The film describes the basic changes that have taken place in farm buildings, including scenes of Frank Lloyd Wright's proposed "unified farm."

Principles of Quality Concrete (37 minutes). Use in Unit 11. This movie describes the essential steps in making quality concrete from the design of the mix to the time the concrete comes from the mixer.

Quality Ready Mixed Concrete (31-1/2 minutes). Use in Unit 10. The film shows

various plant operations involved in producing quality ready mixed concrete and the steps necessary on the part of the contractor and workmen to maintain its quality in the field to produce satisfactory jobs. Many large and small projects, both urban and rural, are shown.

The Road That Can't Rest (22 minutes). Use in Unit 21. This is the story of the network of roads that run through your area. How these expressways, freeways, parkways, or whatever you choose to call them, affect your life is told in this colorful and exciting film.

Tilt-Up Construction on the Farm (15-1/2 minutes). Use in Unit 3. This film is designed as a training aid to show step-by-step methods of tilt-up concrete construction--from excavation to roofing. It contains construction sequences and animation to dramatize building procedures. The film also illustrates the vast range of farm buildings well suited to tilt-up construction. Buildings from many geographic areas are shown in use to dramatize the versatility of tilt-up construction.

Concrete's Finest Fifty Years (32 minutes). The film dramatizes the spectacular role of concrete in the past half century; in structures, highways, farms, water facilities and homes.

HOW TO ORDER FILMS

Just write a postcard or letter to the Portland Cement Association district office serving your area (see list on next page). Specify the title of the film. Print your name and full mailing address. List the first and second choice of dates for your film showing. Please allow at least three weeks for booking. The film will be sent to you postpaid.

Films may be purchased for classroom use. Further information may be obtained from your Portland Cement Association district office.

PORTLAND CEMENT ASSOCIATION SLIDE SET

ABSTRACT - This teaching guide, developed by the Bureau of Industrial Education in cooperation with the Education Advisory Cwmmittee of the California Council of Construction Inspectors Association, is intended for one semester's instruction of persons who will be engaged in the supervision and construction of buildings under construction. The material is divided

into seven units which include: (1) Duties of the Construction Inspector, (2) Structural Wood Materials, (3) Structural Metals, (4) Masonry, (5) Paving, (6) Utilities, and (7) Review and Examination. This document is illustrated with diagrams, graphs, charts, and pictures. A related document is available as VT 013 298 (also in this issue). (GEB)

CHAPTER 2. SUGGESTIONS FOR DEVELOPING GOOD OWNER/AI RELATIONS

4. GET IT STRAIGHT. Misunderstandings usually result from a lack of clear communication. Be sure to come to a mutual agreement with an owner as to just what is to be done. Attention to the following details will usually avoid the ill-will a later disagreement may generate:

a. Itemize the work on a work order or in some manner that will provide a clear understanding of the work to be done.

b. Establish a firm understanding about the cost or range of cost anticipated for the job.

c. If an annual inspection is involved, point out that certain maintenance is required to perform the inspection, such as:

(1) Removal of cowling, inspection plates, fairing, upholstering, etc.

(2) Aircraft and engine to be cleaned.

(3) Disassembly of wheels and other components to determine their condition.

d. Advise the owner that an annual inspection involves determination of compliance with aircraft specifications and airworthiness directives.

e. Agree as to whether routine servicing is to be included as part of the inspection or is to be performed separately. Such servicing may not be a part of the inspection, but may be conveniently done while conducting the inspection. Such items might be:

(1) Cleaning spark plugs.

(2) Servicing landing gear oleos.

(3) Changing oil.

(4) Minor adjustments.

(5) Servicing the brakes.

(6) Dressing propeller blade nicks.

(7) Lubrication.

(8) Stop drilling small cracks and minor patching of cowling and baffles.

STRUCTURAL SERIES #2

This course of study was prepared by the Bureau of Industrial Education at the request of the industry, to meet the needs of persons engaged in the supervision and inspection of buildings under construction. Structural Series No. 2 covers one semester's work. This material was developed by the Education Advisory Committee of the California Council of Construction Inspectors Association. This publication is in draft form and will be refined by the Statewide Committee after it has been tested by various instructors.

This material was prepared under the direction of the following committees:

STRUCTURAL SERIES #2

UNIT I - DUTIES OF THE CONSTRUCTION INSPECTOR

I-A - History of Inspection

Inspections, in some form or another and under a variety of nomenclatures, have been carried on through all ages of history, this being particularly true at various stages of extensive construction carried out by rulers throughout all civilized areas of the world, an example being an overseer for the various Pharaohs during their program of monumental construction, these particular inspectors, of course, being basically concerned with maintaining a force of slave labor.

From that time forward, the complexities of government, use of greater varieties of materials, and creation of guilds (ultimately unions) of various trades have steadily increased the need for intelligent and responsible inspection of all types of construction.

In the State of California, in the current century a massive earthquake occurred in 1933, as a consequence of which inspections became enacted into law relative to all public school construction.

Within the past few years, in this State, the Inspectors have created a statewide association aimed to extend their knowledge and abilities toward better inspection service.

I-B - Qualification

1. Experience:

The major qualification of a good Inspector is his years of experience in construction work of a type similar to that for which he is being assigned.

It is becoming more and more - on large projects - a practice to assign Inspectors on the basis of specialized knowledge, such as mechanical, electrical, concrete work, steel work, etc.; however, large portions of construction projects still require the services of an Inspector with a good general knowledge of all phases of construction.

Experience on that basis would indicate an Inspector drawn from the ranks of construction superintendents.

2. Education:

The need for inspection service is steadily increasing to such an extent that it is becoming more and more difficult to draw men of experience from the ranks of their previous occupations.

As a consequence, younger people, without a great amount of job experience, are becoming interested in this field of work.

21208

Also, it is increasingly evident that the qualifications of an Inspector definitely require the inclusion of a basic and current knowledge of building materials and construction procedure.

Hence, the current presentation of a course of study for construction supervision as presented by the California State Department of Education, Bureau of Industrial Education.

3. Personality:

The prime duty of a construction Inspector is to make sure that construction is performed in accordance with the drawings and specifications. An Inspector has no authority to deviate from the drawings and specifications; however, at the same time, an Inspector should avoid assuming an unreasonable attitude concerning his own interpretation when reasonable doubt exists as to intent, especially concerning minor details.

At all times, the Inspector should bear in mind that the principal objective is the successful completion of the intent of the contract documents. All directions by the Inspector should be based upon obtaining the best possible final result in accordance with the documents.

Accepted and proven construction practices in the use of common sense and good judgment should be the basis of the Inspector's attitude.

The above results can only be successfully obtained by the Inspector through a dignified, quiet, tactful, and firm attitude on his part.

I-C - Duties

Copies of such codes as Uniform Plumbing, Electrical and Safety Codes, Uniform Building Code, local ordinances, etc., must be maintained on the project at all times for the use of the Inspector, the Owner, and the Architect/Engineer.

The Inspector shall set up and maintain files, including a daily diary, Inspector's copies of correspondence, daily reports, the contract form, an approved set of plans, specifications, addenda, and change orders, approved shop drawings, approved samples, concrete placing records, welding records, pile driving records, water, gas, sewer tests, concrete tests, steel tests, progress reports, and other correspondence pertaining to the contract.

Contract documents usually call for (and if not the Inspector should require) a schedule of parts of the work showing the estimated starting and completion dates, all within limits of the time for completion of the contract. As the work progresses, he shall plot on this chart the weekly progress of the work.

21209

UNIT I - DUTIES OF THE CONSTRUCTION INSPECTOR

Whether called for or not by the contract documents, it is imperative for the good of the project that the Inspector keep a daily diary. The prime value of the diary is to cover current actions, attitudes, and conditions while the work is in progress.

It is potentially extremely valuable.

It may be used to advise supervisors of the progress of the work, of any difficulties being encountered, of any non-compliance with the drawings and specifications, and matters of similar nature. Being maintained on file, it will be of use in the event a Contractor requests an extension of time or an increase in contract price, and for audits of work progress.

It is therefore important that the diary be completely filled out in a legible manner and that all pertinent facts be stated percisely. Statements should be so worded that persons reading and evaluating the diary at some future date will be aware exactly what happened and what information the Inspector intended to convey.

The greatest value of this diary is its information over and above current weather conditions, amounts of material received, lists of material in use, or data on the contractor's labor force.

Items to incorporate in a diary:

a. Any oral statement or order given to Contractor's supervisory personnel on behalf of the Architect/Engineer concerning additional work or concerning a controversial item.

b. Warnings given to the Contractor's personnel concerning improper, inadequate, or unsafe methods which are likely to result in injury to personnel or in damage to the Owner.

c. Conditions encountered in excavation, such as change of material from that indicated on the plans, the presence of rock, boulders, or other hard material. The encountering of utility lines not shown on the drawings or, if shown, found in a different location.

d. Any claim the Contractor may make to the Inspector regarding interpretations of drawings and specifications with respect to the inclusion of work or material which he feels is not covered or required.

e. Any materials or equipment rejected because of non-compliance with the specifications. This should include any material or equipment that is found to be defective as a result of tests or analysis.

f. Delays caused by non-delivery of material, equipment breakdowns, weather conditions, insufficient supply of labor, etc. Remarks concerning general progress of the job.

g. Work accomplished by the Contractor, and its location.

21210

Any and all other reports required on the project can be lifted from this diary on the basis of weekly, semi-monthly, or monthly reports. For example, should the particular project be a public school, an additional report on a form provided by the Office of Architecture and Construction is required on a quarterly basis and at completion of a project. This State form is termed a "Verified Progress Report" and formerly was required to be notarized.

The Inspector shall notify the Contractor and Architect/Engineer of any deviation from the approved plans and specifications. Care shall be taken that the Inspector does not issue instructions to the Contractor which will result in a claim for extra compensation or extension of contract time. Such orders will be issued only as contract change orders from the Architect/Engineer's office after proper approvals have been obtained, and any changes in contract price or time have been determined.

The Inspector shall verify that shop drawings and samples of certain materials, and satisfactory reports of tests of certain materials, as required by the plans and specifications and in the instructions to the Contractor are submitted to the Architect/Engineer's office and approved before the materials are incorporated in the work.

The Inspector shall verify percentage of work completed as presented by the Contractor for payment on an approved percentage breakdown form before this information is forwarded to the Architect/Engineer. All items of percentage shall be consistent with work completed. Contract documents usually require that the bidder submit list of subcontractors. Any change in the listed subcontractors should be approved by the Owner and the Architect/Engineer. Work on the job by any subcontractor not listed in the contract documents or properly approved is a violation of the contract and the Architect/Engineer should be advised immediately.

The contract documents provide for monthly payments to be made under the contract on the basis of percentages of work completed, this usually on a form prepared by the Architect/Engineer or by the Contractor and approved by the Architect/Engineer. This monthly estimate and request for payment must be checked for percentage of work completed and approved by the Inspector before it is submitted to the Architect/Engineer's office for certification.

Changes in the plans and/or specifications are a possibility in any contract.

No deviations from the approved plans and specifications shall be permitted until the Inspector receives notification from the Architect/Engineer that the change meets with the approval of all parties concerned.

A formal change in plans and specifications and, if a change in price or time is involved, a change in contract - termed a Change Order - will be prepared and issued by the Architect/Engineer's office.

21211

Occasionally the Architect/Engineer may notify the Contractor to proceed with the change after necessary informal approvals have been obtained, pending approval of the formal Change Order. This information will also be given to the Inspector and will be the Inspector's authority to allow the Contractor to proceed with the change.

The Inspector has no authority to order change in plans, specifications or contract. The above-mentioned Change Orders, which stem from any condition necessitating a deviation from the requirements of the contract documents, must be registered as a Change Order.

The Owner is the only party legally authorized to approve any changes in the work under the contract. This means that no individual has the authority to order a change in the work prior to the approval of the Owner, and the Construction Inspector cannot authorize Change Orders.

Each Change Order, upon approval, becomes a complete supplemental contract document; therefore must be complete in every respect, including the following:

a. Reference as to the party requesting the change.

b. Reason for requesting the change.

c. A detailed description of the proposed change, listing the exact location and nature of the work, or a supplemental drawing attached and referred to on the face of the Change Order.

d. Change in contract amount, if any.

e. Change in contract time, if any.

As-built or record drawings need to be maintained by marking up a set of prints indicating items which may comply with the approved plans and specifications but are not located or indicated in detail, such as the depths of any footings carried below those shown on the drawings, the exact locations and depths of underground and underslab conduits and piping, the location of conduits embedded in concrete or otherwise inaccessible. These as-built or record prints shall be turned over to the Architect/Engineer upon completion of the project, or as requested.

If the project is not completed within the time prescribed in the contract, the Inspector shall make a complete report listing all missing items and work not completed, this to be forwarded to the Architect/Engineer. When the project is complete, the Inspector will review with the Architect/Engineer any and all guarantees, keying instructions, and completion of final punch list items, etc., that are called for in the contract documents. The Inspector must confirm that the above are received by the Owner before the Architect/Engineer can certify the completion of work.

21212

f. Make a written list of all discrepancies found on the aircraft indicating if and how corrected. The owner may want a copy of this list.

g. Discrepancies not corrected that result in the aircraft being reported as "unairworthy" must be listed in duplicate with the original going to the owner and the copy to FAA. The owner should understand that the aircraft is not eligible to be operated without a special authorization until the discrepancies are corrected.

h. Establish a reasonable time period to accomplish the inspection.

i. Request the owner to supply the complete aircraft records for review and entries. Point out that this is necessary to properly conduct an annual inspection.

j. Complete the inspection as soon as practicable. Often an aircraft will sit around the shops waiting for parts, etc., even though the inspection as such was actually finished. In these cases it is advisable to officially report the aircraft unairworthy. (Ref: FAR 43.11(a)(5).) When the parts arrive, the repairs can be completed and the aircraft returned to service in the usual manner. Very often this time lapse represents several weeks, or even months, during which many things can deteriorate on the aircraft. Also, there is always the chance that an AD involving some part of the aircraft may have been issued in the interim. In these cases, it might be unwise to complete the repairs originally intended and sign the aircraft off as "airworthy" without doing another complete inspection.

k. Complete the aircraft record entries as required by sections 43.9 and 43.11 of the FARs. Make adequate descriptions of repairs or alterations if accomplished along with your inspection. It is not necessary to record preventive maintenance; however, anything defined as a repair or alteration should be entered.

l. Record compliance with all Airworthiness Directives actually accomplished. Provide sufficient information so that the owner has that required of him by FAR 91.173(b)(2). A general statement such as "All ADs complied with" is NOT an adequate entry and should be avoided. Many owners keep a separate record of AD compliance in the back of the logbook or a specially provided section. This is a good place to identify those ADs of a recurring nature and when the next compliance is due. See Figures 1 & 2, for typical entries.

m. When approving repairs and alterations, if possible, be available as work progresses on major jobs. This way you can see affected areas and structures better than after completion of the entire job. In many cases the workmanship during the progress of the job can be improved much more easily than having to do it over later.

All questions, interpretations, suggestions and criticisms posed by the Contractor or Inspector shall be directed to the Architect/Engineer, or his field representative.

I-D - Criteria for Good Inspection

The Inspector must keep in mind that the Owner is the only party legally authorized to make any change in the work under the contract. The Architect/Engineer, as part of his service and duties under his contract with the Owner, is completely responsible for all phases of the work to and including the completion of the construction contract.

The Inspector, while an employee of the Owner, must constantly and consistently, to his best ability, keep the Architect/Engineer completely current with all phases of the progress of construction. He serves as the "eyes" for the Architect/Engineer to make sure that the design is carried out as contemplated. He must be alert not only in inspecting the structural phase of the job but must also give careful attention to all phases of the finished work with particular emphasis on mechanical and electrical systems.

The Inspector should not be satisfied with merely reporting mistakes that occur on the job after they are made. He should become so well acquainted with the plans and specifications and with all phases of the project that he can anticipate and prevent costly and time-consuming mistakes and foresee bottlenecks due to delayed delivery of material or improper scheduling of the work.

In this way the Inspector can perform a real service to the Owner, to the Architect/Engineer, and to the Contractor. He thus becomes an important member of the team that it takes to insure a smoothly running construction job, a safe and properly constructed building, delivered on schedule.

The Inspector should keep in mind that the attitude of the public toward the Owner and his building program is influenced by the manner in which he conducts himself. He must be just, fearless, impartial, unprejudiced and constructive. Finally, he should remember that there is a common rule of law that says "in every contract there exists an implied covenant of good faith and fair dealing."

I-E - Relationships

1. In General:

The position of Inspector involves responsibility that requires technique. The following rules should be observed governing personal conduct:

He should not talk about administrative problems connected with the project in public. Such discussion by the Inspector should only be held with appropriate personnel officially connected with the project. (Loose talk is poor relations for all concerned.)

21213

He should be swift and decisive in his actions against violence, negligence, or evidence of bad faith. He should be just as quick to recognize and commend good work.

He shall have no personal connection with and should not accept a loan, gift, nor gratuity either directly nor indirectly from any individual, contractor, subcontractor, group, company, corporation, nor public body that is in any way responsible for compliance with the terms and conditions of the contract.

He shall not use narcotics nor intoxicating liquors while on duty, nor appear on duty under their influence.

He shall not suggest nor recommend for employment any particular person or persons or subcontractor nor should he suggest nor recommend the purchase of any specific material nor product except insofar as the specifications may require.

He should not give orders nor instructions to the contractor nor any subcontractor involving any change in the work not covered by the contract, except upon instruction from the Architect/Engineer with approval of the Owner.

He shall not give orders and instructions to the Contractor nor any subcontractor that in any way involves responsibility for or gives cause for claim against the Owner. He shall not assume the duties of any superintendent nor foreman of the General Contractor nor any subcontractor.

2. Contractors:

An Inspector should understand that as a general rule he should not interfere with the Contractor's method of performing work. Such interference could, to some extent, release the Contractor from his responsibility under the contract for the results obtained.

An Inspector's action ordinarily is limited to the rejection or acceptance of various parts of the work as they are completed. If the Contractor's methods are obviously unsafe, inadequate, or do not comply with established construction practices, the Inspector could warn the Contractor against continuing such methods. Following such warning, if the Contractor continues to use such methods, the matter should be promptly brought to the attention of the Architect/Engineer or his designated representative for further action.

An Inspector should always do business with the responsible superintendent or foreman on the job, and should carefully avoid the issuance of any directions to the Contractor's workmen. At no time should an Inspector take any action which could be interpreted as supervision or direction of the Contractor's operations.

21214

An Inspector should be alert to cooperate with the Contractor in expediting progress of the work; to catch errors in questionable practices in time to avoid future rejection or slowdown of work or material; to observe the Contractor's equipment and operations from a safety standpoint, assisting him in correcting safety hazards. An Inspector's relationship with the Contractor should be cooperative and friendly at all times without compromising the Owner's objective of obtaining high quality construction in accordance with the drawings and specifications, and within the limits of allowable contract time.

An Inspector's actions should show neither favoritism toward, nor discrimination against, the Contractor.

3. Owners:

In almost every case the Inspector is directly an employee of the Owner and as such is fully responsible to the Owner.

By the same token, the Architect/Engineer, in his services to the Owner is completely responsible for the project from its inception to its completion, which puts the Inspector in a position of being responsible to the Architect/Engineer as well.

The Inspector should, as a consequence, at any time that he receives direct orders from the Owner in any phase of the work, such as reports, changes in work or material, etc., be very careful to contact the Architect/Engineer before proceeding with any such issued orders.

4. Architect/Engineer:

The Inspector shall work under the direction of the Architect/Engineer. In his review of plans and specifications, any inconsistencies or seeming errors must be reported promptly to the Architect/Engineer for interpretation and instructions. Should he feel that such interpretations and instructions are not in conformity with the approved plans and specifications, he shall request further clarification.

5. Field Representatives:

Certain Federal, State, Local, and Building Trade representatives periodically visit most projects. These people are in the nature of Inspectors for such organizations as Health, Education and Welfare, Department of Housing and Urban Development, Office of Architecture and Construction, Department of Local Assistance, Fire Marshal, Industrial Safety, County Health Department, Electrical and Plumbing Codes, Trade Unions, etc.

These people should contact the Inspector. If not, the Inspector should be alert to the visits, make himself known and record in

21215

general all conversations and specifically any indicated violation or recommendation of Code, or agency requirement indicated for prompt report to the Architect/Engineer.

I-F - Legal Obligations

Aside from the legal obligations imposed on the Inspector by the terms of the construction contract between the Owner and the Contractor, he has the following legal obligations:

1. To make truthful reports on the forms furnished.

2. To comply with the conditions imposed on his employment as an Inspector by local building departments and/or State agencies.

There is no State licensing law governing Inspectors at the Present time. Should such be enacted, the Inspector will have legal obligations as enumerated therein.

I-G - Tips to Inspectors

1. The Inspector shall carefully study and analyze the terms and conditions of the contract agreement, plans, specifications, and addenda, or interpretations, if any. All inconsistencies or seeming errors in the documents should be reported promptly to the Architect/Engineer for interpretation and instruction.

   The Inspector shall keep a file on the job of all approved plans, specifications, shop drawings, instructions, etc., and he shall immediately return to the Architect/Engineer any unapproved documents for proper action. He shall also keep copies of applicable codes on the job and he shall refer to them from time to time as necessary.

2. The Inspector shall give special attention to the terms and conditions of the specifications relative to the testing of materials. At the start of the project he should obtain the name of the testing laboratory which will conduct the testing of materials for the project. When materials are required to be tested, the laboratory reports showing them to be in accordance with the plans and specifications shall be in his hands before the materials are incorporated in the work except, of course, that concrete is tested as it is placed and reports are received when specified. If any tests do not meet the specification requirements, the Inspector shall notify the Architect/Engineer immediately and request instructions in writing.

3. The Inspector shall inspect all materials immediately upon their delivery to the job. Delivery shall be arranged for such a place and in such a manner so that he can inspect them and so that they will be protected from damage by the weather or other causes and so reject any material not acceptable under the terms of the contract, and notify the Architect/Engineer.

21216

4. The Inspector shall immediately notify the Architect/Engineer in the event he does not feel qualified in passing judgment on questionable material or workmanship. The Architect/Engineer will take the necessary action to provide additional information and/or inspection.

5. When any work is let on a unit cost or cost-plus basis, as provided for in some contracts or in some Change Orders, the Inspector shall keep a daily record in duplicate of all labor and material, including quantities used, and report this information to the Architect/Engineer.

6. The variety and complexity of materials and methods of work requiring inspection suggest that a check list of pertinent items for inspection be prepared for reference by the Inspector as the job progresses. The following is a recommended check list, comprising four basic items:

   I. Structural Work:

      a. The Inspector shall keep a special record of certain phases of the construction procedure, as follows:

         Concrete Placing Operations: The record shall show the time and date of placing of concrete, and the time and date of removal of forms in each portion of the structure. Verify material testing requirements of the A.C.I. Manual of Concrete Inspection, or other applicable codes, for cast in place, precast, prestressed and pneumatically placed concrete. Verify with Architect/Engineer location of cold, expansion, and tooled or weak joints.

         Welding Operations: The record prepared by a certified welding inspector shall include identification marks of welders, list of defective welds, manner of correction of defects, etc.

         Structural Steel: Verify material in accordance with applicable Codes, laboratory tests, erection specifications, field and shop painting, bolted and riveted connection, use of high tension bolts. Note: Use of drift pins, slotting of holes or cutting members to force sections in place is not permitted.

         Driven and Drilled Piling: Driven concrete piles shall be carefully recorded and the penetration under the last ten blows for each pile when piles are being driven. Drilling of concrete piles shall be verified for depth, belling, alignment, cleanness of shaft, and foundation soil material. Support of reinforcing, placing of concrete and cap elevations shall be checked.

21217

Structural Glued Laminated Lumber: All structural glued laminated lumber must be continuously inspected during fabrication by an approved inspector. Verify specified lumber grade marking, timber connections and approved types of glue and gluing methods.

b. Layout:

Check general instrument layout for accurate locations of property lines, building locations, easements, grades, floor lines, drainage, etc.

Verify utility service locations.

Check contiguous street, curb and sidewalk work.

Record completely field conditions of any existing work or landscaping on site to be maintained during building operations.

Verify soil and foundation conditions indicated on the drawings.

Verify excavations, specified undisturbed foundation areas, and over excavation.

Verify and record specified compaction of soils with soil laboratory.

II. Architectural Work:

a. Asphaltic Concrete:

Verify Drainage patterns indicated on drawings.

Verify specified base materials and surface treatment with poisons.

Verify compacted thickness, and compaction methods and equipment.

Verify temperature of hot aggregate.

Surface seals.

b. Fencing: Check installation and wire ties for alignment and safety (avoid sharp edges, finger catching shapes, etc.).

21218

c. Roofing:

Verify roof drainage.

Verify roof materials and weights

Make complete roof deck check inspection

Check temperature of roofing asphalt.

Check cleanup of asphalt drippings.

Check manufacturers' and roofers' warranties.

d. Plastering Work:

Check lathing attachment, grounds, metal trim mould, use of galvanized and high rib lath, metal stud anchorage, and any specified boxes, ducts, etc.

Check adequate protection at adjacent finish surfaces during plastering operations.

Verify plaster mixes, materials and thickness either hand or pneumatically placed.

Check control of curing with specified moisture spray.

Check drying of interior plastering work with adequate mechanical drying equipment, if required.

e. Mill Work:

Check for adequate care and protection of finish mill work delivered to site.

Verify secure anchorage of wall cabinets.

Check installation of finish hardware.

Verify delivery to Owner of specified key systems, identified.

f. Ceramic Tile Work:

Verify specified grades of material, shapes, colors and patterns.

Check sub-slab, wall backing, floor drains.

Check location and threshold materials.

21219

g. Terrazzo Work:

Check sub slab, wall backing, location of floor drains, and drainage, etc.

Check location of divider strips.

Check adequate protection of plumbing, fixture finishes contiguous to ground surfaces.

h. Metal Sash and Doors:

Verify specified bonderizing or other special finishes.

Check adequate and proper protection of sash delivered and installed on job.

Check alignment and proper operation of sash and doors.

Check seal-vents and caulking compounds.

Check weather tight sealing of exposed metal doors.

i. Sheet Metal:

Verify gauges and materials.

Check location of expansion joints.

Verify specified cleaning and priming.

j. Glass and Glazing:

Verify glass grade, thickness and pattern and caulking compounds.

Check installation of all glazing points, clip bars, beads and angles.

Check back putty, true clean installation of putty work, free of cracks, etc.

k. Acoustical Tile:

Verify pattern, finish and fire rating of specified material.

Check layout pattern of tile.

Check true surface and edge scribing (against diagonal or edge lighting).

21220

1. Resilient Floors:

Check filling and cleaning of sub floor surfaces and base backing.

Verify flooring materials.

Check floor patterns and alignment with Architect.

Check threshold materials and location.

Check final waxing and adequate protection of finished floor.

m. Painting Work:

Check and verify specified preparation of surfaces and materials:

Back priming;
Galvanized metal;
Waterproofing;
Iron and steel;
Masonry, concrete, stucco;
Interior plaster;
Pigmented and clear finishes.

Test for hot plaster, surfaces and moisture content of materials to be painted.

Check for adequate protection of adjacent finished surfaces.

Review complete color schedule with Architect.

Check specified professional sign painting.

III. Electrical Work

a. The Inspector shall notify the Architect and Electrical Engineer at the following principal stages of electrical installation or as required by specifications:

When Contractor commences to install large conduit in underground trenches.

Before any work is to be closed in.

When Contractor commences pulling high voltage cable and making splices.

When complex control wiring is begun.

When electrical work is completed and being tested.

b. The Inspector should watch the following for compliance with specifications:

Conduit:

Galvanized or sherardized. (Not black.) Check label on conduit.

Flexible conduit only where specified.

Rigid conduit where specified.

E.M.T. (thin-wall) conduit only where specified.

Fiber and transite conduit in trenches should be level, straight, supported by spacers and tied to prevent floating. Alignment should be maintained during pouring of concrete envelope.

No debris or rocks dumped in conduit trenches during backfilling

Check for contact of conduit with soil; see specifications for requirement of concrete envelope or wrapping, particularly at couplings and fittings.

No unnecessary bends in conduit; check against flattening bends.

Check required large radius bends for telephone and electric service.

Reaming and elimination of burrs from cut conduit.

Swabbing, cleaning and pulling of test mandrels through fiber, and other conduit.

Installation of pull wires in empty conduits.

Grounding of systems as specified.

Outlet Boxes:

Flush and plumb.

Excessive use of extension rings where tile or brick occurs is not acceptable.

Secure mounting.

Verify elevation and locations to clear cabinet work, splashes, base and other finishes. Verify all

21222

February 9, 1966. Total time 445 hours. Complied with AD 64-27-2 by installing new rubber float, and new bowl cover screws. Inspected solder on float valve bracket and found okay. Stamped -64 on nameplate.

George B. Jones

George B. Jones IA 272182

FIGURE 1.

Typical entry for compliance with an Airworthiness Directive with one-time compliance.

February 9, 1966. Total time 352 hours. Complied with AD 61-23-1 paragraphs a(1) and a(2) by tapping and magnifying glass. No cracks found. Void on top of blade #2, B2-248-53A, S/N 123, is 2" long and extends from 25" to 27" outboard of blade butt rib. Next inspection due at 377 hours.

George B. Jones

George B. Jones IA 272182

FIGURE 2.

Typical entry for compliance with an Airworthiness Directive with recurring inspection.

elevations and locations shown on drawings. Check location of conflict with other items.

Cast pull boxes for work exposed to the weather where specified.

Wire:

Compare type and size stamped on wire with specifications and plans.

Check use of temperature rated wire in high temperature locations requiring heat resistance insulation where specified.

Check use of higher temperature rated wire where branch circuits pass through thuroescent fixtures adjacent to ballasts. (Ballast heat will damage ordinary insulation.)

Do not allow high voltage cable to be bent sharper than specified minimum radius in pull boxes or during installation.

Do not allow wires with nicked or damaged insulation to be installed.

Lubricant for pulling heavy conductors must only be an approved cable lubricant.

All connections to be soldered except where connectors are specified.

All connections completely and neatly taped. Splices to be properly made and joints to be tight when splice connectors used, only approved type.

Required slack in conductors at all panels, equipment and pull boxes. (Required slack in underground pull boxes is one complete turn around the sides of the box.)

Placement of required pull wires.

Receptacles and Switches:

Check catalog numbers on packages with specifications.

Watch for special outlets for specific uses.

21223

Lamps and Fixtures:

Check color of fluorescent lamps with specifications.

Check security of all fixture mountings, also for swivels and sway adapters as specified.

Check fixtures for type, size, defects and required mounting heights.

Type of ballast must conform to specifications.

Underground Pull Boxes:

Check elevation and surface drainage before installation.

Check sealing of cover.

Panels:

Good practice requires main terminal connectors to be retightened 24 hours after original tightening.

Wire cables to be neatly arranged. Color coding as required.

Panel schedules to be neatly identified with circuit descriptions, with panel designation typed at top.

Doors or covers to fit tight and secure.

Grounding:

Check tightness of all ground connections.

Require all ground connections to be accessible.

All equipment to be securely grounded.

Bonding strips required for motor grounding where motor is connected with flexible conduit and voltage to ground is over 150 volts (this applies to 220-volt and 440-volt, 3-phase systems, but is not required on 208, 3-phase systems).

General:

Name plates on all equipment.

Delivery of proper operating instructions.

Check for proper working clearance in front of panels, switchboards, motor controls, etc.

21224

Coordinate underground piping and ductwork routing, elevations, slope and arrangements so as to accommodate other trades.

Inspecting underground piping and ductwork and requiring Contractor to correct or replace defective materials or workmanship.

c. Verify testing all systems as they are put into operation.

IV. Mechanical Work

a. The Inspector shall keep the Architect and Mechanical Engineer advised as to the status of the job by notifying him at the following principal stages of construction:

When Contractor commences underground work.

When Contractor begins installation of ductwork.

When plumbing, heating and ventilating is roughed-in and the buildings are ready for lath and plaster.

When Contractor commences to install finish plumbing and heating.

When plumbing, heating and ventilation or refrigeration work is completed and ready for testing.

b. The Inspector should watch for the following:

Pipe and Fittings:

Materials used are as specified.

Joints are made as specified.

Wrapping of joints and underground piping where specified.

Piping is supported as specified.

Water piping is isolated from hangers and supports as specified.

Piping is properly flashed.

Insulation is installed as specified.

Installations by other trades to avoid damage to piping, etc.

21225

Valves:

Installed where and as specified or approved.

Unions are installed where and as specified.

Make sure that all building shut-off valves are properly located and installed in access boxes and identified.

Plumbing (General):

Make sure contractor has roughed in all waste, water and gas lines for all fixtures and equipment and that all specified tests have been satisfactorily completed, before any lathing and plastering is done.

Make sure fixtures are supported as specified, with proper backing and supporting arms.

Have Contractor sterilize water supply system as soon as possible after plumbing fixtures and trim are set, where specified.

Check earth compacting around pipes for possible damage to lines and soundness of backfill.

Check danger of shear loads on C.I. piping.

Spacing of hangers (close to hub, etc.).

Wrapping of pipe and electrolysis considerations as specified.

Installation of insulation on chilled lines as specified.

Sound insulation of pipes.

Check access to cleanouts, valves, drainage of lines, vents, installation of equipment guards, etc.

Check specified identification of lines, valves, etc.

Secure required operating instructions, supplies, etc.

Heating (General):

Make sure piping is installed as specified.

Do not allow Contractor to change arrangement of equipment piping or valves from that shown on the drawings without first being approved by the Engineer.

21226

Check clearances of gas fired equipment and gas vents from combustible materials.

Name plates on all equipment.

Delivery of proper operating instructions.

Ventilation (General):

Check gauges of sheet metal being used.

Make sure installation of sheet metal work conforms with specifications.

Check for the installation of duct turns and air extractor before it is concealed or becomes inaccessible and check fire dampers in ductwork for installation and accessibility.

Check performance of Contractor air balance testing readings.

Name plates on all equipment.

Delivery of proper operating instructions.

21227

PHYSICAL PROPERTIES

WOOD STRUCTURE

Wood is an aggregate of cells, essentially cellulose in composition, which are cemented together by a substance called lignin. Although wood cells vary in shape and size according to their function, the greater portion are elongated and are positioned vertically in the standing tree. Known as fibers in hardwoods and tracheids in softwoods, wood cells vary from about 1/25 to 1/3-inch in length, and 1/100 of these dimensions, in width.

Hardwoods and softwoods have horizontally positioned bands of cells called rays. These are usually evident on quarter-sawed surfaces and are more conspicuous in some species than others. They provide a pleasing pattern where visible.

HARDWOODS AND SOFTWOODS

Native trees are divided into two classes - hardwoods which have broad leaves, and softwoods or conifers, which have scalelike or needlelike leaves. Hardwoods, except in the warmest regions, shed their leaves at the end of each growing season. Softwoods, except cypress and larch, are evergreen.

The terms "hardwood" and "softwood" do not necessarily apply to the hardness or softness of the wood. In fact, some species of hardwoods have softer wood than some of the species of softwoods while certain softwoods are as hard as the medium density hardwoods.

Principal commercial softwoods and hardwoods in the United States are listed in the table of weights, page 6

HEARTWOOD AND SAPWOOD

The end of a log shows three distinct zones, the bark, a light-colored zone just beneath it called the sapwood; and an inner zone, often darker in color, called heartwood. At the structural center of the heartwood is the pith or "heart center" as it is termed in the lumber trade. When the pith is enclosed in a piece of lumber it is called "boxed pith", when it is not, the piece is termed "side-cut".

A tree increases in diameter by forming new layers of cells at the outer surface of the sapwood. Here a thin band of tissue called the cambium lays down new bark cells toward the outside and new wood cells toward the inner or sapwood side.

The young tree is composed primarily of sapwood which functions in sap conduction and food storage. As the tree increases in diameter, inner sapwood cells cease their conductive function and form the inactive heartwood. Deposits in these inactive cells give the heartwood of many species a darker color than the sapwood.

As all heartwood was once sapwood, there is no consistent difference between heartwood and sapwood in weight when dry or in strength. Inclusions in the cells, however, make heartwood more durable when in contact with soil and under other conditions conducive to decay. Where wood is to be treated with preservative, however, deeper and more effective penetration can be attained in sapwood.

ANNUAL GROWTH RINGS

The activity of the cambium tissue in forming new wood is influenced in temperate zones by the growing season. Through winter months the tree is dormant. In the spring, however, the cambium begins to lay down thin walled cells with large cavities. Through the summer cell walls increase in thickness and cell cavities decrease in size until growth virtually ceases in the fall. Differences in cell wall thickness between those last formed in the fall and the thin walled new cells formed the following spring results in rings of annual growth which are apparent on cross sections of all native woods.

Annual rings vary in width according to growth conditions. Narrow rings are formed during short dry seasons and wider rings occur when growing conditions are more favorable.

Annual growth rings appear on the ends of "boxed pith" timbers as concentric circles around the pith or heart center. On side cut (pithless timbers) rings appear as arcs of circles whose centers would be located at the pith in the log from which timbers were obtained.

SPRINGWOOD AND SUMMERWOOD

In many woods two distinct areas are visible in each ring of annual growth: (a) an inner light colored portion, known as springwood; and (b) an outer darker portion, known as summerwood.

The springwood is composed of the large cavitied thin walled cells formed during the early part of each growing season. The thicker walled cells formed later in the year make up the summerwood portion. As the summerwood contains more solid wood substance than springwood, it usually appears darker in color. Springwood and summerwood bands are usually most noticeable in the dense softwood species.

In these species the proportion of springwood and summerwood present has an important effect upon strength properties and physical characteristics.

DENSITY AND RATE OF GROWTH

In the softwoods commonly used for structural purposes the rate at which trees grow; i.e., form new wood substance, has an important effect on their strength properties. An accurate measure of this is provided by the relative width and character of wood in each annual growth ring.

In such woods pieces having medium to narrow growth rings generally have higher strength properties than those having wide rings. In addition, pieces in which a considerable portion of each annual ring is made up of dense darker summerwood are recognized as having higher strength properties than pieces with a lower percentage of summerwood. Therefore, in grading structural material for use under known loads, the rate of growth (number of rings per inch) and the density (proportion of summerwood) are considered and made a part of the specification. Material having a specified minimum number of annual rings per inch is termed "close-grained" and that having, in addition, one-third or more summerwood is termed "dense".

GRAIN AND TEXTURE

The terms "grain" and "texture" are used in various ways to describe the characteristics of wood. Wood from slow growing trees in which annual growth rings are narrow is sometimes described as "close-grained"; that from rapidly growing trees with wide rings as "coarse-grained". This is another way of describing the number of rings per inch in strength grading.

Straight grained and cross grained describe wood in which the direction of the fibers (not annual rings) are parallel to, or at an angle with, the sides of the piece. Cross grain includes a spiral grain where fibers wind around the trunk of the tree. The expression "slope of grain" is employed in the grading of structural lumber to describe the extent of cross grain permitted as slope of grain has an important influence on strength.

PHYSICAL PROPERTIES

"Grain" and "texture" refer usually to appearance rather than strength. Fine grain is used to describe woods in which cells are small and thick walled making a compact wood with smooth surface. Coarse grain woods have cells which are large and open, producing a porous surface where pores are cut at an angle to their longitudinal axis.

Lumber sawed in such a manner that the annual rings when viewed from the end of the piece form an angle of 45° or more with the wide faces is described as edge-grain, vertical grain or rift-sawn in softwoods, and as quarter-sawn or comb-grained in hardwoods.

Edge grain softwoods and quarter-sawed in hardwoods

Flat-sawed in softwoods and plain-sawed in hardwoods

(Courtesy of U.S. Forest Products Laboratory)

The term "flat grain" or "plain-sawed" describes lumber in which the annual rings are at an angle of 45° or less with the wide faces of the piece. "Bastard-sawed" in hardwoods is lumber having both plain-sawed and quarter-sawed portions, thus falling midway between true quarter-sawed and true plain-sawed stock.

WEIGHT OF WOODS

Specific Gravity

Solid wood substance is heavier than water, its specific gravity being about 1.5 regardless of the species of wood. Despite this fact, dry wood of most species floats in water because a portion of its volume is occupied by air filled cell cavities.. Variation among species in the size of cells and in the thickness of cell walls affects the amount of solid wood substance present and hence, the specific gravity. Thus, specific gravity of wood is a measure of its solid wood substance and an index of its strength properties. Specific gravity values, however, may be somewhat affected by gums, resins, and extractives, which contribute little to strength. The relationship of specific gravity to wood strength is evident in the practice of assigning higher basic stress values to lumber designated as "dense".

Weights of Wood

Weights of sawed or round timbers are approximate because of moisture content, density and sapwood thickness variations within the piece. Average weights per cubic foot of various commercial woods, at 12 per cent moisture content, are given in the following table. Weight of individual pieces will vary from these averages and are also different at other moisture contents. Green weight represents the weight of wood in the standing tree.

Weight in Pounds of Commercially Important Woods Grown in the United States

Species	*Average weight per cubic foot based on weight and volume at a moisture content of 12 percent.
Alder	28.5
Ash, black	34.9
Ash, white	42.2
Aspen(1)	26.8
Basswood	25.8
Beech	43.8
Birch, sweet	46.7
Birch, yellow	43.0
Butternut	27.0
Cedar, Alaska	31.1
Cedar, Eastern red	32.9
Cedar, incense	24.9
Cedar, Port Orford	29.6
Cedar, Western red	22.9
Cedar, Northern white	21.4
Cherry	35.5
Chestnut	30.1
Cottonwood, black	24.2

MOISTURE IN WOOD

Wood may contain moisture in two forms: As "free water" in the cell cavities and as "absorbed water" in the capillaries of the cell walls.

When green wood begins to lose moisture, the cell walls remain saturated until the free water has been evaporated. The point at which evaporation of free water is complete and cell walls begin to lose their moisture is called the "fiber saturation point" (fsp). This point occurs between 25 and 30 percent moisture content for most species.

Moisture in wood is expressed as a percentage of the oven dry weight and is determined most accurately by weighing a representative sample, drying it at slightly over 212° until no further loss of weight takes place, reweighing, and then dividing the difference between the original and final weights by the final (oven dry) weight. Electric moisture meters offer a simpler though less exact method of determining moisture content.

With slight seasonal variations, wood in use over a period of time attains an equilibrium moisture content (emc) corresponding to the humidity of the surrounding atmosphere. When exposed to similar atmospheric conditions, different woods will have the same moisture content regardless of their density. The following chart shows the moisture content of wood when in equilibrium with various relative humidities at given temperatures.

Moisture content has an important effect upon susceptibility to decay. Most decay fungi require a moisture content above fiber saturation point to develop. In addition, a favorable temperature, an adequate supply of air, and a source of food, are essential. Wood that is continuously water-soaked (as when submerged) or continuously dry (with a moisture content of 20 per cent or less) will not decay.

Moisture content variations above the fiber saturation point have no effect upon the volume or strength of wood. As wood dries below fiber saturation point and begins to lose moisture from the cell walls, shrinkage begins and strength increases.

21230

PHYSICAL PROPERTIES

Shrinkage

Shrinkage of wood takes place between fiber saturation point and the oven dry condition. It is stated as a percentage of the original or green dimension. Where wood is installed at approximately the moisture content it will attain in service, only minor dimensional changes occur. These are caused by absorption or release of moisture due to atmospheric changes.

Wood shrinkage is greatest in the direction of the annual growth rings (tangentially), somewhat less across the rings (radially), and very little along the grain (longitudinally). Longitudinal shrinkage is usually a small fraction of 1 per cent and is too small to be of practical significance.

Shrinkage of commercial softwood boards across the grain averages about 1 per cent for each 4 per cent change in moisture content. Shrinkage of hardwoods is slightly greater.

Large structural members shrink proportionately less than smaller lumber because drying does not take place simultaneously in the inner and outer portions of such pieces. The inner portion which dries more slowly than the outer section prevents the wood near the surface from shrinking normally. Later, when drying of the interior occurs, outer layers which have become set in drying, prevent the inner portion from shrinking to the extent that it would normally.

In softwood structural lumber, 6" x 6" or larger in cross section, a shrinkage of approximately 1/64" per inch width of face may be expected in drying from green to average equilibrium moisture content in service.

Hardwood structural lumber may shrink slightly more than these amounts.

Effect on Strength

Increase in strength begins when the cell walls begin to lose moisture; that is, as the wood is dried below the fiber saturation point. From this point most strength properties increase rapidly as drying progresses.

Drying wood from green to 5 per cent moisture content often doubles and in some species triples end crushing strength and bending strength. However, increase in strength with seasoning is greater in small clear specimens of wood than in large timbers. In the latter, increase in strength may be offset to some extent if checking develops in seasoning.

Other strength properties are not equally affected by changes in moisture content. Although some properties, such as crushing strength and bending strength, increase greatly with seasoning, others, such as stiffness, change moderately. Shock resistance, an exception, shows only slight change as wood dries.

The following table presents the average variation in strength properties of wood for 1 per cent change in moisture content.

Average Increase (or Decrease) in Wood Strength Properties for a 1-percent Decrease (or Increase) in Moisture Content Below Fiber Saturation Point.*

Property	Change per 1-percent change in moisture content (percent)
	Percent
Static bending	
Fiber stress at proportional limit	5
Modulus of rupture, or cross-breaking strength	4
Modulus of elasticity or stiffness	2
Work to proportional limit	8
Work to maximum load or shock-resisting ability	1/2
Impact bending	
Fiber stress at proportional limit	3
Work to proportional limit	4
Height of drop of hammer causing complete failure	1/2
Compression parallel to grain	
Fiber stress at proportional limit	5
Maximum crushing strength	6
Compression perpendicular to grain	
Fiber stress at proportional limit	5-1/2
Hardness, end grain	4
Hardness, side grain	2-1/2
Shearing strength parallel to grain	3
Tension perpendicular to grain	1-1/2

21231

PHYSICAL PROPERTIES

*HEAT TRANSMISSION THROUGH WOOD

The property of heat transmission through wood called thermal conductivity varies with density and moisture content and to an extent with wood structure. As with most materials thermal conductivity of wood increases with increased moisture content and with increased density.

At a moisture content of 12 per cent, thermal conductivity of commercial softwoods and hardwoods varies from 0.65 to 1.22 Btu per hour, per inch of thickness, per square foot, per degree F. temperature difference between opposite faces.

*SPECIFIC HEAT OF WOOD

The specific heat of wood is the ratio of the thermal capacity of wood substance to that of water at 60°F. The coefficient of thermal capacity of water at 60°F. is one British thermal unit (Btu) per pound per degree (Fahrenheit) change in temperature, i.e., the amount of heat required to raise the temperature of a pound of water one degree Fahrenheit is one Btu.

Specific heat of oven dry wood substance is substantially the same at any given temperature for all species of wood. In experiments on 20 species of wood, which included softwoods and hardwoods, average specific heat within the temperature range of 32° to 223°F. was found to be about 0.33, i.e., an average of 0.33 Btu was required to raise the temperature of a pound of dry wood one degree Fahrenheit.

The specific heat of wood increases in an approximately straight line relation with increase in temperature. Therefore, if a more accurate value for the specific heat of oven dry wood than the average value 0.33 is desired, it may be computed from the formula:

$c_t = 0.266 + 0.000644\,(t - 32)$, in which

c_t = the specific heat at a temperature of "t" degrees Fahrenheit

t = the temperature at which the specific heat is desired.

The quantity of heat "H" (Btu) required to raise the temperature of 10 pounds of dry wood substance from "t_1" degrees Fahrenheit to "t_2" degrees F. is equal to $10\,(t_2 - t_1)\,(c_t)$ Btu.

Average specific heat (c_t) of oven dry wood for any range of temperatures can be determined from the equation:

$$c_t = 0.266 + 0.000322\,(t_2 + t_1 - 64)$$

where t_1 and t_2 refer to initial and final Fahrenheit temperatures, respectively.

For wood containing moisture, thermal capacity may be obtained by determining the amount of heat required to produce a given change in temperature in a unit volume of wood on the basis of its oven dry weight and the amount of heat necessary to produce the same temperature change in the included water. This can be expressed mathematically as follows:

$H = m\,(t_2 - t_1)\,(c_1 + \frac{M}{100})$, in which

H = total heat requirement (Btu)

c = average specific heat for the temperature range $(t_2 - t_1)$

m = oven dry weight of wood (pounds)

M = weight of included water expressed as a percentage of the oven dry weight "m" of the wood

*ELECTRICAL PROPERTIES

Dry wood is an excellent insulator against transmission of direct electrical current and low frequency alternating current. Electrical resistance of wood, however, varies appreciably with wood moisture content. Variations in the distribution of a fixed amount of moisture in the area of measurement also have a considerable effect upon electrical resistance. Variations in species, specific gravity and amount of inorganic ash content have a much smaller effect upon electrical resistance.

Below fiber saturation point (24 to 31% moisture content) electrical resistance of wood increases very rapidly with decrease in moisture content, whereas above fiber saturation point electrical resistance changes much more slowly. Resistance is also affected by temperature, approximately doubling with each drop of 22-1/2°F.

Electrical resistivity (specific resistance) of a material is the electrical resistance in ohms between opposing faces of a cubic centimeter unit. Electrical resistivity of wood varies from 10^8 ohm-centimeters at 16% moisture content to 3×10^{18} at the oven dry condition.

Dielectric Constant. The ratio of the capacitance of a condenser having a wood dielectric to the capacitance of the same condenser with a vacuum dielectric is termed the dielectric constant for the wood used. Dielectric constant values differ along the grain from across the grain, being as much as 30 per cent greater in the parallel-to-grain direction.

Increases in wood density and in moisture content both result in appreciable increase in dielectric constant values. The capacitance type of moisture meter is based upon the variation of the dielectric value of wood with corresponding moisture content changes.

Resistivity of Wood at Radio Frequencies. Low frequency parallel resistivity of wood is much greater than corresponding resistivity at high (radio) frequencies. The resistivity (r) of wood is approximately inversely proportional to the frequency (f) as evident in the following equation where the power factor ($\cos \phi$) and the dielectric constant (ϵ) vary only slightly with frequency:

$$r = \frac{1.8 \times 10^{12}}{\epsilon f \cos \phi}$$

This reduction in resistivity with increase in current frequency is the principle upon which the curing of glue lines in wood by radio frequency heating is based.

Where wood is employed as a dielectric (as in high-frequency gluing) the power (P) dissipated in the wood as heat is proportional to the capacitance of the condenser (C), the power factor of the wood ($\cos \phi$), the voltage (E) and the frequency (f). This is indicated in the equation

$$P = 2\pi f E^2 C \cos \phi$$

As high voltage (E) in the foregoing equation is difficult to generate, presents insulating problems and tends to produce arcing, the power (P) necessary to produce heat is best increased by increasing the current frequency ($\cos \phi$). The heat thus generated affords a rapid means of polymerizing synthetic resin wood glues.

CHAPTER 3. BASIC FUNCTIONS OF THE AI

5. GENERAL. The basic functions of the AI are set forth in section 65.95 of the FAR. This section permits an AI to approve major repairs and major alterations, conduct annual inspections, and to perform or supervise progressive inspections in accordance with the standards and procedures set forth in FAR 43.

   a. The AI may not approve major repairs or major alterations on any aircraft maintained in accordance with a continuous airworthiness program under Part 121 or 127 of the FARs.

   b. The AI is permitted to perform one other function set forth in section 21.183(d) of FAR 21. This section permits AIs to perform an airworthiness inspection on single-engine airplanes, prior to issuance of an airworthiness certificate. The scope of the inspection is comparable to the 100-hour inspection.

6. APPROVING MAJOR REPAIRS AND ALTERATIONS. The AI's primary responsibility is to determine airworthiness by inspecting for compliance with pertinent Airworthiness Directives (ADs) and Aircraft Specifications or Data Sheets; that repairs or alterations conform to approved data, and the aircraft is in a condition for safe operation.

   a. The AI should conduct this inspection himself as the regulations do not provide for delegation of this responsibility.

   b. The approval should not be taken lightly as a paper signoff. It should consist of a detailed investigation to determine the material used, quality of workmanship, compliance with approved data, completeness, and possible effect on other structures or systems. The finished product should be at least equal to its original or properly altered condition.

   c. The approval of alterations by AIs is often a misunderstood term. The AI cannot approve the DATA for major alterations. He may, however, inspect to see that the alteration conforms to data PREVIOUSLY APPROVED BY THE ADMINISTRATOR. (FAR 65.95.) This means the AI must assure that data is available as a basis for approval. Preferably, this should be prior to beginning the repair or alteration. If data is not available, or you are not sure that the data you have is acceptable, discuss it with your local FAA inspector. The inspector may be able to:

5B05 2098

PHYSICAL PROPERTIES

*CHEMICAL COMPOSITION OF WOOD

Wood is a complex aggregate of compounds which may be segregated into two major groups, those which make up the cell structure and other substances known as extractives or infiltrated materials.

The cell wall components of wood consist of carbohydrates and a cementing substance known as lignin. The carbohydrates consist of cellulose and hemicelluloses, while the exact chemical composition of lignin is unknown. In addition to carbohydrates and lignin, cell wall composition also consists of a small amount of mineral matter which remains when wood is subjected to complete combustion. The principal minerals are calcium, potassium and magnesium and small amounts of sodium, manganese, iron and aluminum. The most abundant compound, however, is calcium oxide which comprises one-half to three-fourths of the total ash. The best known compound, however, is potassium carbonate or potash, which is of value as fertilizer and in the manufacture of soap.

The extraneous materials in wood are those which can be removed by neutral solvents such as water, alcohol, benzol, ether and chloroform. These include oils, acids and fats, tannins, dyestuffs starch and nitrogenous materials known as alkaloids. The natural durability of some woods is closely related to the toxicity of certain of these extractives.

*THERMAL EXPANSION OF WOOD

Seasoned wood like most other solid materials expands and contracts with changes in temperature. The coefficient of thermal expansion (increase in dimension per unit of measurement for a temperature rise of one degree Fahrenheit) differs in the three structural directions of wood. Longitudinally, the values are independent of the specific gravity and vary from about 1.7×10^{-6} to 2.5×10^{-6} per degree Fahrenheit for different species. Across the grain the values vary from 25×10^{-6} to 45×10^{-6} per degree Fahrenheit, varying directly with the specific gravity.

The coefficient of thermal expansion varies slightly with temperature but for all ordinary uses may be considered constant. In the longitudinal direction thermal expansion of wood is from 1/10 to 1/3 as great as the expansion of metals, concrete and glass for the same temperature change. Thermal expansion values for wood across the grain are generally greater than along the grain but usually less than values for other structural materials.

In most structural design the coefficient of thermal expansion of wood can be neglected. Thermal expansion is of importance only in the case of special structures that are kept dry and are subjected to considerable temperature change.

MECHANICAL PROPERTIES*

MECHANICAL PROPERTIES

The mechanical or strength properties of wood are of importance in structural design. They are a measure of the ability of wood to resist externally applied forces which tend to alter its shape, size or result in any other deformation. Mechanical properties determine the applicability of wood in structural as well as many other uses where resistance to bending, compression, tension, shear and other effects of external forces is required.

The various mechanical properties are briefly described herein as general information, their quantitative values and determination usually being a matter of laboratory investigations and tests made in accordance with established procedure. Test results are interpreted in the data used as the basis for structural design or other service requirements. The allowable unit stresses recommended for the material investigated are examples of such interpretation.

Mechanical properties of wood considered in these data are:

Bending Strength under Static and Impact Loads

Tensile Strength Parallel and Perpendicular to Grain

Compressive or Crushing Strength Parallel and Perpendicular to Grain

Shear Strength

Stiffness

Hardness

Resistance to Cleavage

OTHER FACTORS

Position of Growth Rings

Timber from Live and from Dead Trees

Effect of Resin and Turpentining

Comparative Strength of Air-dried and Kiln-dried Wood

Effect of Preservative Treatment on Strength and Permanence

DEFINITIONS

Force

Force is that power which changes or tends to change the state of rest or motion of a body or causes a body to change its shape if held in place by other forces.

Work

Work is the product of force and distance, or force acting through distance.

Stress

Stress is a distributed force. It is a measure of force per unit area.

Fiber Stress

Fiber stress is the distributed force tending to compress, elongate or change the relative position of wood fibers.

Tension Stress

Tension stress is an internal stress induced by forces which tend to elongate the affected member.

Compression Stress

Compression stress is an internal stress induced by forces which tend to crush or shorten the affected member.

Shear Stress

Shear stress is an internal stress induced when opposing forces tend to cause adjoining planes or surfaces of a member to slide, one on the other.

Allowable Unit Stress

Allowable unit stress, variously called safe working stress, working stress and allowable stress, represents the maximum stress which may be safely induced in columns, beams and other structural parts. It is the stress per unit of section area used as the basis of design computations and is the proportional part of the ultimate stress which experience, investigation and tests have indicated as being safe to use.

Strength

In the broad sense, the term "strength" embraces those properties of wood which enable it to resist imposed forces or loads. In a more restrictive sense, strength applies to any one of the mechanical properties, i.e., strength in shear, strength in compression parallel to grain, strength in compression perpendicular to grain, strength in bending or hardness, etc.

Bending Strength

Bending strength is a measure of the load carrying capacity of a beam.

Bending Stress

Bending stress is a compound stress induced by loads acting perpendicular to the longitudinal axis of a member or other loads which tend to cause the member to deflect as a beam. It is a composite of the simple stresses, i.e., compressive, tensile and shear.

Fiber Stress in Bending

Fiber stress in bending is the computed stress in a wood member subjected to loads which cause deflection.

Stiffness

Stiffness is the property which enables a member acted upon by external forces to resist deformation.

MECHANICAL PROPERTIES

Flexibility

Flexibility is the quality which renders a material capable of being appreciably bent without breaking. It is not the exact counterpart of stiffness, however, as toughness and pliability are also involved.

Elasticity

Elasticity is the property which permits changing form with the application of force and immediate recovery upon release. In any elastic material the deformation is proportional within limits to the force applied.

Proportional Limit

Proportional limit is the limit below which deformation is proportional to the applied load. Beyond the proportional limit value deformation increases by a greater percentage than the increase in load. Because a member stressed within the proportional limit recovers from its deformation upon removal of the load, the proportional limit is also known as the "elastic limit".

Bending loads or loads in compression parallel to grain which produce stresses in excess of the stress at proportional limit will ultimately cause failure if they continue to act on a wooden member.

STATIC BENDING

Resistance of a wood beam to slowly applied loads is measured in static bending tests.

Stress at Proportional Limit, Static Bending

The fiber stress at proportional limit in static bending is the computed stress in the wood member beyond which the induced strain is no longer proportional to the stress or applied load.

Modulus of Rupture, Static Bending

Modulus of rupture is the computed maximum fiber stress in the extreme upper and lower fibers of a beam at the maximum load. It is a measure of the ability of the beam to support a slowly applied load for a short time. Modulus of rupture is not a true stress since the formula by which it is computed is based on assumptions which are only valid within the proportional limit.

Since the modulus of rupture is based upon the maximum applied load, values can be determined more precisely than proportional limit values.

Modulus of rupture values for clear wood in conjunction with results of tests on larger members containing knots and other strength reducing characteristics are used in determining safe working stresses for structural timbers.

Modulus of Elasticity, Static Bending

Modulus of elasticity is a measure of the stiffness or rigidity of a material. It is the ratio of stress per unit area to corresponding strain per unit length within the proportional limit.

High modulus of elasticity indicates a stiff material. In beams, deflection under load varies inversely as the modulus of elasticity, that is, the higher the modulus, the smaller the deflection. Modulus of elasticity is used in computing deflection of beams, joists and stringers where imposed loads do not result in stress beyond the proportional limit. It is also used in computation of allowable loads for columns.

Work to Proportional Limit, Static Bending

Work to proportional limit in static bending is a measure of the energy absorbed by a beam when it is stressed to the proportional limit. Since work is the product of force times the distance moved, work to proportional limit involves both load and deflection at the proportional limit. It is a comparative property which indicates the ability of wood to absorb shock without permanent damage.

Work to Maximum Load, Static Bending

Work to maximum load in static bending represents the capacity of a member to absorb shocks which cause stress beyond the proportional limit and are of sufficient magnitude to cause permanent deformation. It is a measure of the combined strength and toughness of the material under bending stresses. Work to maximum load is closely related to height of drop of the test load in impact bending as a measure of toughness or shock resistance.

Work to maximum load, as well as work to proportional limit, cannot be used directly in design. Their usefulness is limited to comparisons.

Total Work, Static Bending

Total work in static bending is a measure of the toughness of wood when loaded to complete failure. Like work to maximum load, it is a measure of that quality involving shock resistance. It is also indicative of that quality measured by height of drop of the test load in impact bending.

IMPACT BENDING

Relative elastic behavior and other properties of wood beams when subject to shock are measured by impact bending tests.

Stress at Proportional Limit, Impact Bending

The stress at proportional limit in impact bending is the computed stress in a beam when impact loads reach the proportional limit. Such values average more than twice as great as similar values from static bending tests.

Work to Proportional Limit (Elastic Resilience), Impact Bending.

Work to proportional limit in impact bending is a measure of the energy a beam absorbs in being stressed to proportional limit by impact loads. It is used to compare the ability of a timber to absorb shock and recover promptly without injury, and applies only to conditions in which stress is applied and removed in a fraction of a second.

Height of Drop Hammer, Impact Bending

Height of drop hammer to cause complete failure in impact bending gives a comparative figure expressing the ability of wood to absorb shock which cause stress beyond the proportional limit.

21235

MECHANICAL PROPERTIES

COMPRESSION PARALLEL TO GRAIN

Compression parallel to grain is a measure of the capacity of a short column to withstand loads acting in a direction parallel to the long axis.

Stress at Proportional Limit, Compression Parallel to Grain

Stress at proportional limit is the greatest stress at which the compressive load remains proportional to the shortening of the specimen. It is the limiting stress in compression parallel to grain which should not be exceeded in determining safe loads. Stress at proportional limit in compression parallel to grain is taken into account in arriving at safe working stresses for columns and other compression members, and in determining design values for bolted and other joints.

Maximum Crushing Strength, Compression Parallel to Grain

Maximum crushing strength is the maximum ability of a short piece to sustain a slowly applied end load over a short period. This property is important in estimating endwise crushing strength of wood and in developing safe working stresses for structural timbers and design of joints.

COMPRESSION PERPENDICULAR TO GRAIN

Compression perpendicular to grain is a measure of the bearing strength of wood across the grain.

Stress at Proportional Limit, Compression Perpendicular to Grain

Stress at proportional limit is the maximum across-the-grain stress of a few minutes duration which can be applied without injury to the piece through a metal plate covering but a portion of the timber surface. It is useful in deriving safe working stresses in compression perpendicular to grain, for computing the bearing area of beams, stringers, and joists, etc.

In deriving proportional limit stresses in compression perpendicular to grain, test load is applied on the radial surface of test specimens. Experience has shown that the supporting action of wood fibers in the unloaded area adjacent to the bearing plate results in an increase in stress over that which occurs if load is applied to the entire area of the specimen. The stress obtained in this standard test is about 50 per cent greater than that obtained in loading the entire area of the piece being tested. As the ratio of loaded to unloaded areas is decreased, further increase in proportional limit stress is obtained. This is evident in derivation of safe working stresses where higher stress values are permitted for bearing areas less than six inches in length.

SHEAR STRESS

Maximum Shearing Strength, Shear Parallel to Grain

Shear strength parallel to the grain is a measure of the ability of wood to resist slipping of one part upon another along the grain. Derivation of this stress is accomplished by loading a 2" x 2" portion of a 2" square wood block 2-1/2" long on a 3/4" projection as indicated in the accompanying sketch.

Horizontal Shear

Horizontal shear stress is important in the design of beams, especially those of short span and deep section. It is the resistance to the tendency of the upper half of the beam to slide upon the lower half when the beam is loaded. In a beam of rectangular section the maximum tendency for horizontal shear occurs at the neutral axis of the section.

TENSION PARALLEL TO GRAIN

Available results of tension tests show that, generally, ultimate tensile strength values exceed values for modulus of rupture. Modulus of rupture values, however, are used as a conservative estimate of the ultimate tensile strength parallel to grain as it is difficult to devise attachments which permit tensile strength of the full cross-section of the wood member to be developed.

TENSION PERPENDICULAR TO GRAIN

Tensile strength perpendicular to the grain is a measure of the resistance of wood to forces acting across the grain which tend to cause splits or cleavage. Strength of a specimen of wood in this respect is determined by measuring the force required to produce failure. Maximum load divided by the smallest area over which the load is distributed provides the tensile strength of the specimen. Strength values measured in this manner are of use in estimating the resistance of wood to the splitting action of bolts and other fastenings.

HARDNESS

Hardness is a measure of the resistance of wood to indentation. The term is also used to indicate the ability of wood to withstand abrasion, and in this connection is related to toughness.

The measure of hardness is the load required to imbed a 0.44-inch hardened steel ball to one-half its diameter in the wood. It represents a property important in wood

MECHANICAL PROPERTIES

subjected to wear and marring, such as flooring, furniture, railroad ties, paving blocks, etc. There is no significant difference between radial and tangential hardness. End hardness, however, generally exceeds that obtained from tests on the sides of the specimen.

CLEAVAGE

Cleavage in wood is defined as the resistance offered to splitting. It is related to tension perpendicular to grain but differs in that the acting force is concentrated at the bottom of the cleft rather than being uniformly distributed over the surface of failure. The stress, obtained by dividing the force required to produce failure by the width of the split surface, is measured in pounds per inch of cleft surface. Resistance to cleavage is important where wood must hold nails or screws.

TORSION

The torsional strength of wood is little used in structural design. It is the internal moment of resistance which develops when a member is twisted by an external force tending to cause rotation about its longitudinal axis. Torsion plays a secondary role in the analyses of wood beams which show a tendency to buckle.

OTHER FACTORS

POSITION OF GROWTH RINGS

In sawing lumber and timber the position of growth rings may be made to assume different directions with respect to the surfaces of the piece.

Bending

Tests in bending indicate little difference in the strength properties of wood regardless of whether the rings as viewed on the end of a piece are vertical or horizontal.

Compression Parallel to Grain

Values from tests in compression parallel to grain have shown that wood members with growth rings in any position were practically equivalent in strength.

Compression Perpendicular to Grain

In compression perpendicular to grain the principal variation affected by the position of growth rings occurs in the modulus of elasticity. Indications are that differences in proportional limit and in maximum crushing strength perpendicular to the grain are considerably less than for modulus of elasticity.

TIMBER FROM LIVE AND FROM DEAD TREES

Sound wood from trees killed by insects, fungi, wind or fire, unless unduly checked, is as good for any structural purpose as that from trees which were alive when cut.

In considering the utility of timber from a dead tree it is helpful to remember that the heartwood of a living tree is essentially dead, and in the sapwood only a portion of the cells are functional. The important consideration is not whether the trees from which timber products are cut are alive or dead but whether the timber itself is free from decay or other defects that would render its wood unsuitable for use. This is determined by careful inspection.

EFFECT OF RESIN AND OF TURPENTINING

Resin is formed in some of the conifers and especially in the southern pines. Amounts up to 6 per cent of the dry weight of the wood are common and pieces with a resin content up to 50 per cent are sometimes found.

Tests at the Forest Products Laboratory indicate that resin will slightly increase some strength properties but that the effect is too small to be of any practical significance. An excessive amount of resin, however, is sometimes associated with an injury such as compression failure which may substantially reduce strength.

The results of a special investigation involving mechanical tests and physical and chemical analyses of the wood of turpentined and unturpentined trees from the same locality show that (1) turpentined timber is as strong as unturpentined timber of the same species for like densities; (2) the weight and shrinkage of the wood is not affected by turpentining; (3) except in parts adjacent to "faces" where there may be a concentration of resin, turpentined trees contain neither more nor less resin than unturpentined trees. As the exudation of resin occurs only from the sapwood, the resin content of the heartwood is not affected by the turpentining process.

COMPARATIVE STRENGTH OF AIR DRIED AND KILN DRIED WOOD

Comparative strength tests by the Forest Products Laboratory on kiln-dried and air-dried specimens show that good kiln-drying and good air-drying have the same beneficial effect on the strength of wood.

For certain uses it is possible to dry wood to a lower moisture content by kiln-drying than is practicable through air seasoning. Since most strength properties of wood increase with loss of moisture, higher strength values may thus be obtained from kiln-dried material than are possible from air-dried wood. This difference in strength, however, is not permanent when the wood is used for the same purpose, since, in use, wood will eventually reach the same moisture condition regardless of whether it is kiln-dried or air-dried.

EFFECT OF PRESERATIVE TREATMENT ON STRENGTH

Coal-tar creosote and the various creosote mixtures used as wood preservatives are practically inert with respect to wood substance and have no chemical influence upon it which affect its strength. Also, standard water-borne preservatives in the concentrations commonly used in preservative treatment have no important effect on the strength of wood. Care should be taken, however, that the severity and duration of the heating and pressure conditions to which wood is subjected in receiving treatment do not exceed those which are known to be satisfactory.

PERMANENCE

All structural materials are subject to attack by certain destructive agents. Most metals must be painted to resist corrosion. Wood, while being exceptionally resistant to corrosive action, can be made more resistant to attack by fungi, insects and marine borers by adequate preservative treatment when used where the hazard from these agencies is severe. Protection from attack by wood destroying agents may also be provided by proper methods of construction and by the selection and use of naturally resistant species.

21237

MECHANICAL PROPERTIES

Lignin, cellulose and other constituents of wood substance exhibit little or no change or loss with time when wood is adequately protected from the elements and other destructive agents. Color, however, may be slightly changed by long and continued exposure to air.

The effect of time on strength cannot be accurately appraised by tests of wood from old structures as the original strength of the material is generally unknown. Evidence from tests of sound aged wood as are on record indicate that no significant loss of strength has occurred.

A survey of wood bridges has shown that literally hundreds of these structures made entirely or partly of wood have served satisfactorily and with but little attention for long periods of time. Many bridges that are more than a century old are still in service. Others have been replaced while still in good condition because of the demands for greater width of roadway and higher load capacity than that for which they were constructed.

Association and others. The U. S. Forest Service and others maintain test plots to make compensative evaluations of various preservatives, treated and untreated wood. AWPA standards are based upon the long time record service life of different commodities in actual use which has been treated with the many preservatives.

Preservatives are grouped into three types, 1) Creosote and creosote solutions, 2) Oil-borne and 3) Water-borne.

The creosote type preservatives include straight creosote, creosote-petroleum solutions and creosote-coal tar solutions. This type is most commonly used to treat poles, piles, railroad ties, bridge and wharf timbers. Wood, pressure treated with creosote and creosote solutions was the first mainly used approved preservative. Some creosote marine piling in New York Harbor is still in use after 80 years. Creosote timber foundation piles are considered permanent.

The oil-borne types include, 1) Pentachlorophenol, 2) Copper Napthenate, and 3) Solubilized Copper-8-Quinalinolate. Pentachlorophenol is the most commonly used and is available from most commercial treating companies. The petroleum oils will vary from heavy fuel oil to mineral spirits, and most recently a new process has been developed using liquid petroleum gas as a carrier.

Pentachlorophenol in heavy oil is commonly used to treat utility poles. It is increasingly used for piles other than marine. Using either a light petroleum solvent or liquid petroleum gas as a carrier, producers have included additions to make it also water repellant. Copper-8-Quinalinolate is commonly used to treat lumber which may come in contact with produce or foods. Copper Napthenate is most commonly used for brush application.

Water-borne preservatives consist generally of inorganic chemicals which are carried into the wood via water solution. These preservatives are commonly used for treatment of lumber and plywood used in building construction. They have the advantage of no odor and can be painted when dried after treatment. Most commercial treating companies treat with one of these preservatives. Some are more resistant to leaching when in ground contact and offer a longer expectant service life. These latter preservatives are becoming more popular for treatment of poles for pole buildings.

The heartwood of some species of trees contain chemicals which impart some protection. The degree of protection will vary by the amount of toxic chemicals endowed by nature. Lumber cut from old-growth timber and selected from the butt area will usually contain the greater amount of chemicals. Heartwood

21239

cut from the following species are considered to be the most naturally resistants:

Bald Cypress	Chestnut
Cedars	Black Locust
Junipers	Mesquite
Redwood	Red Mulberry
Pacific Yew	Osage Orange
Catalpa	Black Walnut

The heartwood of the species listed below are usually classified as moderate in decay resistance and provide good service under milder conditions such as siding or similar above ground uses:

Douglas fir	Southern yellow pine
Eastern White Pine	Sweet gum
Honey locust	Western larch
Sassafras	White oak

The wood preserving industry was built on the idea of imparting longer life in all species as well as to sapwood and heartwood alike so that forests could be conserved and wood could be economically used in broader applications. Even though it is more difficult to treat heartwood than sapwood, most all commercially available species can be adequately treated by pressure process. Species having heartwood, which is most difficult to treat, are first incised so that the preservative may enter the closely spaced incisions. Thus, the preservative may be distributed to the required depth of penetration.

21240

UNIT II - STRUCTURAL WOOD MATERIALS

II-A - Wood Preservatives

3. Decay and Insect Attack

There are several preservatives which have been tested and approved for inclusion in nationally recognized standards. These preservatives must be placed deeply into the wood at a high concentration where they can offer adequate protection. The minimum recommended depth of penetration and retention will vary by use, species of wood, and preservative.

Standards such as the American Wood Preservers Association Manual of Recommended Practice have been in almost constant development since AWPA was organized in 1904. It reflects these years of experience and the results of tests conducted by the U. S. Forest Service, universities and others which are for the purpose of evaluating preservatives and results of treatment. These standards establish the minimum penetration, retention and the preservatives recommended for the various species intended for such uses as railroad ties, bridge timbers, marine and foundation piles, utility poles, posts, lumber and plywood used above and in the ground.

The permeability of wood will vary greatly by species and can vary along the surface of any single piece of wood. In addition, the heartwood is always more difficult to penetrate with a preservative than is the sapwood. In view of this, it is apparent that either the wood must be carefully selected so that this material can be uniformly and easily penetrated or these variables must be overcome by conditioning prior to treatment and/or by using the pressure process method of treatment. Pressure treatment eliminates erratic and shallow penetrations resulting in premature failures caused by checks or abrasion exposing the untreated wood.

There are over 300 commercial pressure treating plants located throughout the United States which are equipped to process wood in the form of poles, piles, sawn timber, plywood and glu-lam. This method of treatment also permits special conditioning treatments which prepare the wood to be more receptive to the actual preserving process. The wood is treated in metal cylinders usually 6 to 9 feet in diameter and up to 150 feet long. They are typically built to withstand working pressures of 250 to 300 pounds.

Nonpressure treating processes are not equivalent to pressure treating processes, but can be safely relied upon when used for millwork treated under the quality program of the National Woodwork Manufacturers Association.

Several preservatives are in common use. All AWPA approved preservatives have been subject to extensive test by the U. S. Forest Products Laboratory, Bell Laboratories, American Railroad

21242

(1) Establish an acceptable approval basis, or

(2) Approve the data himself, or

(3) Recommend application for a Supplemental Type Certificate (STC) as the circumstances warrant.

d. Quite often repairs are performed that are eventually covered by fabric, metal skin, or other structure. AIs should have all access needed to make a valid determination of compliance with the approved data. The commonly accepted practice for repairs that are to be covered allows the AI to inspect before the repair is obscured and to make an entry to this effect on the reverse of the FAA Form 337. An example of this appears as Figure 3. When the repair is completed, the final inspecting AI can determine that the inaccessible portions of the repair were done in accordance with FAA approved methods and have been properly inspected.

e. Minor deviation from approved data is permissible IF the change is one that could be approved as a minor alteration when considered by itself. Be sure to list the deviations when completing the aircraft records. When in doubt, contact the local FAA inspector. He may decide the change is not minor and would need specific approval or amendment of the original approval.

f. Approved data to be used as a basis for approval of repairs and alterations may be one or more of the following:

(1) FAA Publications. FARs, Aircraft Specifications, Type Certificate Data Sheets, Advisory Circulars, etc.

(2) Supplemental Type Certificates. A summary is available that lists those STCs which the holders have said will be made available to the public. See Appendix 1.

(3) Parts Manufacturing Approval. Identifies FAA-approved replacement parts.

(4) Technical Standard Orders. Conformity to TSOs indicates FAA approval of materials and appliances.

(5) Airworthiness Directives. FAA-approved data for mandatory action concerning deficiencies found in service.

(6) Manufacturer's Instructions, Kits, and Service Handbooks. Such instructions must bear indication of being FAA-approved when pertaining to major alterations.

Framing - Ordering practices, methods of distribution (whsl. dist. yard), sample specs.

Yard Lumber - Sample specs. for commons and finish items; protection at site

(3) Job Site Protection from Weather and Damage

Framing and Timbers

a. Unseasoned - protect lumber piles or units from contacting soil and keep them straight and even until use

b. Seasoned - protect lumber piles or units from contacting soil and store in protective covers provided by the manufacturer or cover with some type of water repellent tarp.

Finish items - store in area and/or manner to protect from weather or other elements. Allow flooring, paneling, interior trim, etc., to adjust to moisture conditions of room before installation from 1-2 weeks.

II-C - PLYWOOD

(Reprinted from "Plywood Properties, Designs and Construction" by Nelson S. Perkins, C.E., unless otherwise noted)

1. PHYSICAL AND MECHANICAL PROPERTIES

It should be emphasized that the data contained herein are applicable only to plywood complying fully with the appropriate U.S. Commercial Standards.

Durability. Exterior type plywood is as durable as the wood of which it is made. So far as is known, only strong alkalis or acids will break down an Exterior glue, in which cases the wood itself will usually be attacked.

Approved Interior type plywood is designed to withstand temporary exposures normally encountered during construction and, in certain construction grades, to have a reasonable resistance to mold and bacteria through the use of a toxic adhesive.

Both types of plywood must have adequate bond strength to resist expansion and shrinkage stresses due to climatic variations.

Bending Strength and Stiffness. The construction of a plywood panel by cross-laminating veneers and gluing them together capitalizes on the more desirable physical and mechanical properties of wood. The strength of wood along the grain is many times greater than that across the grain. The cross-laminated construction, by providing longitudinal grain both lengthwise and crosswise, also provides bending strength and stiffness in these directions.

The strength and stiffness lengthwise will be somewhat less than for solid wood, but crosswise strength and stiffness are significantly increased over solid wood, being about twice as great in 3-ply 3/8" panels and almost six times as great in 5-ply 3/4" panels.

21245

Racking Resistance. Plywood also functions effectively in its own plane as a structural bracing material. (See 4.b. for the structural diaphragm concept of this action.)

Racking resistance is another term for this bracing action on a wall, roof, or floor that is sheathed with plywood or other structural material.

Actually, although 5/16" is the minimum recommended, 1/4" plywood sheathing on a standard stud-framed wall provides twice the stiffness and twice the strength furnished by 1" diagonal boards, long recognized as adequate. This superior racking strength of plywood was demonstrated first some years ago in a series of tests* by the U.S. Forest Products Laboratory.

Shear Strength and Nail Bearing. Two properties stemming directly from its cross-banded construction are mainly responsible for this superiority of plywood as a structural bracing. First is its high shear strength in all directions perpendicular to panel faces, and second is plywood's relatively high nail bearing, even when nails are within 3/8", or even less of the panel edge.

Similarly, splitting is impossible lengthwise or crosswise, since no cleavage plane can exist.

Impact Resistance. Plywood functions well under impact or heavy concentrated loads, due to distribution of stress by the crossed veneers, over a wide area of the panels

*See "Guide to Improved Framed Walls for Houses" by Alan D. Freas, Senior Engineer, U.S. Forest Products Laboratory, reprinted from "Engineering News Record," Oct. 17, 1946. ----- B.M.S. No. 104, tests on lightweight prefabricated construction.

21246

This can be important in sheathing, sub-flooring, wall sheathing under shingles, and exterior siding directly over studs, as well as in wall paneling and various industrial uses.

Dimensional Stability. This is another benefit from plywood's cross-laminated construction.

Wood has virtually no expansion or contraction along the grain, even with large moisture content changes, whereas across the grain it has considerable. Accordingly, in plywood, any tendency for veneers to expand or contract crosswise is greatly minimized by one or more adjacent veneers running lengthwise.

Obviously, a thin veneer, in changing dimension crosswise, exerts less force than a thick one, and accordingly is more easily restrained by the veneers bonded to it at 90°. It follows that panels with a low percentage of veneers lengthwise (i.e., "parallel plies") will shrink or expand less across their width than panels with a high percentage of lengthwise veneers.

The expansion of a plywood panel consists of a uniform restrained swelling across the main part plus a less restrained swelling at the edges. As might be expected this edge-effect varies directly with the thickness of veneers having grain parallel with the edges. Regardless of panel construction or size, this edge-effect can be estimated at a maximum of 0.012" at each edge for thick (1/16") veneer, and at half (0.006") of this for 1/12" veneer.

The internal, uniform dimensional changes in a panel are approximately proportional to changes in moisture content within the ranges of 6% to 18%.

The total expansion both across the width and along the length of a 48" x 96" panel from 6% (a dry condition) to 18% moisture content may be expected to average between 0.05" and 0.09".

Under an extreme range of moisture conditions (seldom encountered), the dimensional change may be 50% greater. Under normal variations of from 8% to perhaps 14%, however, such changes should average between about 0.03" (1/32") and 0.05" (1/20").*

Concentrated Loading. Puncture tests reported by the American Plywood Association** in 1959, using a 1" loading disc, showed 3/8" panels, (long edges unsupported) over framing spaced 16" center to center, taking loads of 600 to 660 lbs., at edges, and 644 to 1010 lbs. midway between framing. Similarly 5/16" showed ultimate loads of 300 to 600 lbs. at edges and 400 to 550 lbs. at center of span.

Such loads are safely above those to be anticipated for normal plywood sheathing or siding use.

One-half inch subflooring in a series of tests took loads of 732 to 1268 lbs. at unsupported edges, and 600 to 1505 lbs. at center of span.

Thermal Changes. Plywood, like wood, is also subject to dimensional changes due to changing temperature.

---

*Values from Product Research Laboratory, Services Div., American Plywood Assn.

**Laboratory Report No. 59--Concentrated Load Tests on Plywood Subfloors.

21248

Wood expands about ten times as much across the grain as it does parallel, where dimensional changes are quite small.

In plywood, consequently, thermal expansion along the face grain is somewhat greater than in wood, because of the influence of the crossbands. In a typical 96" long Douglas fir panel (5 equal plies), the expansion caused by a 120° F. rise in temperature should average approximately 0.021 inches. This is about 40% more than for plain Douglas fir wood, but still rather insignificant for most cases. On the other hand, across the grain, it is close to 0.029", which is only about 1/6 that for plain wood.

Acoustical. Plywood also rates reasonably well both in absorbing sound and in reducing sound transmission. Plywood 1/4" thick on each side of a 2" x 4" stud wall, has a sound transmission loss of 31.3 decibels*. The sound absorption of this wall varies from about .10 at high frequencies to .31 at low, which compare favorably with other common materials.

Warping and Bowing. Unequal absorption of moisture along panel edges, unequal exposure of opposite faces to moisture, or their unequal painting or coating, may all lead to arching or bowing of panels, as well as to twisting or warping. Unbalanced construction, such as use of different species or thicknesses and diagonal grain in crossbands and faces, may also be a contributing factor. As noted in the next section under "Checking," protection of panel from uneven moisture changes is one of the best preventives.

---

*Tests at Riverbank Laboratories, Geneva, Illinois

21249

Checking. Checks may occur in any wood surface and may attain significant open width under adverse conditions. They may appear on a plywood surface in the form of hairline cracks or even slightly open splits. Under severe moist and dry conditions, such as on unpainted, unprotected panels exposed to the weather, checks may in time become open cracks penetrating virtually the full thickness of the face.

Causes. A certain potential checking occurs during manufacture in the unwinding and subsequent flattening out of the veneer.

Moisture changes, however, are the prime cause of objectionable checking. Under high humidities, the exposed veneer surface expands, while the under surface, glued to the crossband, is held relatively fixed. The expanding exposed fibers push against one another and acquire a "compression set." Then, as the fibers dry out and shrink, they pull away from each other, creating checks of different intensity. These can be more severe under rapid drying than under slow drying since wood is a somewhat plastic material.

Remedies. The remedy, and a most important one which should always be observed, is to avert exposure to extreme variations from the moisture content of the panel at time of manufacture, i.e., about 5 to 9% for hot-press Exterior or Interior, and about 13% for cold-press Interior.

Obviously, panels should be protected from dampness or moisture, either during transit or later storage.

Panels shipped to a job site require protection from elements. They should be protected from ground moisture as well. This will also prevent mold attack.

21250

In addition, certain treatments, such as conventional painting and water-repellent dips to be discussed later, will minimize moisture absorption and loss, and thus permit control of checking within acceptable limits.

Insulation. Plywood renders a wall airtight because of the sparsity of joints, and, by preventing air leaks and drafts, contributes to room comfort. It also has favorable thermal insulation properties, a resistance (1/k) of 1.28 generally being used. This is the temperature difference between the two surfaces of a material that will transmit one btu per squ. ft. per hr., per inch of thickness, through the material.

Since plywood is used generally in panel thicknesses of 1/4" and 3/8", exterior walls may require added insulation. This should be computed for the complete wall assembly since comparisons of separate materials may be quite misleading.

Workability. Plywood is easily worked, cut to various sizes and shapes, and may be bent to fairly sharp radii. It may be finished in a great variety of ways.

21251

2. MANUFACTURE

The softwood plywood industry, once confined to Western Washington and Oregon now utilizes Douglas fir, Southern pine and Western softwoods timbers from forests south to California and east to the Atlantic seaboard. The larger trees in these forests provide the "peeler" logs which, through a scientific manufacturing process, are transformed into plywood. About 195 mills are engaged in plywood production. Their aggregate annual production capacity exceeds sixteen billion square feet (3/8" rough basis).

The manufacture is accomplished by cutting selected logs into "blocks," usually about 8-1/2' long and from 16" to 50" or more in diameter. The blocks are placed in a giant lathe and rotated against a long knife which peels the wood in long, continuous veneer sheets, mostly 1/10" to 3/16" thick. The veneer is belt-conveyed to clippers, cut into desired widths, then run through long dryers which reduce the moisture content usually to 2% or 3% up to about 6%.

Next, after careful grading, the veneer goes to the glue spreaders where, after the cross-bands have been passed between two rotating cylinders with grooved rubber facings that spread glue evenly and in desired amounts on both sides of the veneer, it is laid crosswise into panels of balanced construction, i.e., symmetrical about the center as to thickness and generally as to species. These are inserted into a huge hydraulic press, where pressure of about 150 psi is applied. After removal from the press, panels are trimmed to exact size and, if to be of a sanded grade, are run through large drum sanders to emerge as finished plywood.

NOTICE

Weight and balance or operating limitation changes shall be entered in the appropriate aircraft record. An alteration must be compatible with all previous alterations to assure continued conformity with the applicable airworthiness requirements.

8. DESCRIPTION OF WORK ACCOMPLISHED *(If more space is required, attach additional sheets. Identify with aircraft nationality and registration mark and date work completed.)*

1. Removed right wing from aircraft and removed skin from outer 6 feet. Repaired buckled spar 49" from tip in accordance with Figure 8 in the manufacturer's structural repair handbook #18-1.

   DATE: January 5, 1966, inspected splice in item 1 and found it to be in accordance with data indicated. Splice is okay to cover.

   George B. Jones
   George B. Jones, IA 272182

2. Primed interior wing structure and replaced skin P/Ns 63-0085, 63-0086, 63-0087R with same material, 2024T3, .025" thick. Rivet size and spacing all the same as original and using procedures in Section 3 of AC 43.13-1, dated 1965.

3. Replaced stringers as required and installed 6 splices as per figure 10 in handbook #18-1.

4. Installed wing, rigged aileron, and operationally checked in accordance with maintenance manual.

5. No change in weight or balance.

END

☐ ADDITIONAL SHEETS ARE ATTACHED

FAA AC 65-60B1

FIGURE 3.

Reverse of FAA Form 337 showing typical entries. Note the specific references in identifying FAA approved or acceptable data. Also note the entry regarding inspection of the repair by an AI prior to the cover being applied.

3. ADHESIVES

Exterior Type Plywood. Exterior type plywood, comprising about one-third of production, is made only with a hot-pressed phenolic resin adhesive which becomes permanent and insoluble under practically any exposure condition, including boiling. It is designed for permanent exterior exposure.

Interior Type Plywood. Interior type plywood, comprising the other two-thirds of production, is made for the most part with protein glues having a soya bean-blood base. Most of this (about 45% of the total production) is now hot-pressed, while only about 12% to 14% is cold-pressed. Another 4% to 5% is hot-pressed with extended phenolic resin adhesives, while a small percentage is bonded with urea resins.

Interior plywood is designed both for withstanding temporary wetting during construction, as where used for sheathing and sub-flooring, and, of course, for permanent interior service, provided the wood is not exposed to continued dampness where the moisture content of wood or plywood might exceed 20%. For added protection agains mold, several Interior grades, i.e., C-D sheathing concrete form B-B (Plyform*), Underlayment and C-D Plugged are all manufactured with mold-resistant adhesives if conforming to the U.S. Commercial Standards

21253

4. GRADES

Each type is manufactured in several appearance grades to fit a wide variety of uses. Designation of these grades is based primarily on the quality of the veneer used on the face and back.

All softwood or structural plywood conforming to the Commercial Standards is built-up of veneer from one or more of five classes of veneer, ranging from N (the highest) through A, B, C, and D (the lowest).

Most veneer may be repaired to raise its quality to a higher class. Repairs consist of various sizes and shapes--more often oval or circular--of patches, plugs, and long, narrow shims, nearly always of sould wood which fill voids in the veneer sheet or replace characteristics such as knots and pitch pockets.

Veneer Grades

"N"Grade - a somewhat specialized veneer used for natural finish; varies from clear veneer to sheets with only a few small well-matched repairs.

"A" Grade - a smooth "paint" grade permitting a number of neatly-made repairs, plugs, patches, etc., with certain restrictions.

"B" Grade - a "solid surface" veneer, except for specified minor characteristics;

Typical characteristics permitted in veneer.

"A" Grade

"B" Grade

21254

may have a considerable number of neatly-made repairs; may be generally described as suitable for concrete form work where a smooth surface is desired.

"C" Grade

"C" Grade - the lowest quality of veneer permitted in any Exterior type panel; commonly used also as face of sheathing grade panels. Permits 1" knotholes, tight knots up to 1-1/2", 3/16" splits tapering to a point, and other minor characteristics.

"D" Grade

"D" Grade - The lowest quality of veneer permitted in any Interior grade. Permits 2-1/2" knotholes, pitch pockets 2" x 4", tapering splits up to 1/2", and restricted white pocket of specified degree and extent.

Plywood Grades. Plywood grades* are indicated by two letters, such as "A-D", meaning a panel with an A face and a D back. The inner plies for any Interior grade are also D or better, and for an Exterior panel, "C" or better.

A guide for selecting the proper grades for various uses is shown in Table 1, p. 8.

---

*See U.S. Commercial Standard CS45-60, Tables 1 and 2, for details of various grades of Douglas fir plywood, and CS122-60, Tables 1 and 2 for grades of Western softwood plywood; and CS 259-63, Tables 1 and 2 for grades of Southern Pine plywood.

21255

Panels in most grades are run through large drum sanders, where they are sanded smooth for appearance and on both sides, of course, for balance.

The sheathing grades, however, the most important construction items, are generally left unsanded for greater stiffness and strength as (see copy. There was no more.)

GRADE USE GUIDE TABLE

	GRADE	DESCRIPTION AND SUGGESTED USES	FACE	BACK	INNER PLIES
EXTERIOR TYPES	A-A	Use where the appearance of both sides is important. Fences, built-ins, signs, boats, cabinets, commercial refrigerators, shipping containers, tote boxes, and ducts.	A	A	C
	A-B	For uses similar to EXT-A-A panels, but where the appearance of one side is less important.	A	B	C
	A-C	Use where the appearance of only one side is important. Siding, soffits, fences, structural uses. Box car and truck lining and farm buildings.	A	C	C
	B-B PLYFORM®	Concrete form grade, with high re-use factor. Red painted edges, mill-oiled unless otherwise specified.	B	B	C
	B-C	An outdoor utility panel. For farm service and work buildings. Box car and truck linings, containers, and agricultural equipment.	B	C	C
	C-C PLUGGED	Use as a base for resilient flooring, mosaic tile, carpeting, where unusual moisture conditions exist, such as bathrooms, utility rooms, kitchens. Use for conventional or single layer subfloor-underlayment. Other uses include pallets, pallet bins, and farm service buildings.	C PLUGGED	C	C
	C-C	Unsanded grade with waterproof bond. Use for backing, rough construction, farm service buildings, crating, pallets, and pallet bins.	C	C	C
INTERIOR TYPES	A-A	For interior applications where both sides will be viewed. Built-ins, cabinets, furniture, and partitions.	A	A	D
	A-B	For uses similar to INT-A-A panels, but where the appearance of one side is less important and two smooth surfaces are necessary.	A	B	D
	A-D	Interior use where appearance of only one side is important. Paneling, built-ins, shelving, partitions, and flow racks.	A	D	D
	B-B PLYFORM®	Re-usable form plywood. Glue is moisture-resistant, not waterproof. Green painted edges, mill-oiled unless otherwise specified.	B	B	C
	B-B	Interior utility panel used where two smooth sides are required.	B	B	D
	B-D	Interior utility panel used where one smooth side is required. Good for backing, sides of built-ins. Industry: separator boards and bins.	B	D	D
	UNDER-LAYMENT	Base for resilient flooring and carpeting. A backing material where moisture is not a problem. Used for conventional or single layer subfloor-underlayment.	C PLUGGED	D	C OR D
	C-D	Unsanded structural grade panel for sheathing, subflooring, limited exposure crates, containers, pallets, and dunnage.	C	D	D
	EXTERIOR GLUE C-D	Same as C - D , but with waterproof glue. Not a substitute for Exterior-type plywood	C	D	D
	2-4-1®	Combination subfloor and underlayment. Base for resilient finish flooring, carpeting, and wood strip flooring. Available in square edges; or with tongue and grooved sides or sides and ends. Use 2-4-1 with Exterior Glue in baths, kitchens or utility areas where moisture may be a problem (or when construction delays are anticipated).			

21256

5. PLYWOOD SHEATHING-STORAGE*

Storage. At job site, stack plywood flat on a dry, level platform under shelter. PROVIDE FOR FREE AIR CIRCULATION. Tightly wrapped coverings prevent air circulation. When exposed to the sun this creates a virtual "steam chamber" which is a condition for mold fungi. Long-time storage should be indoors in flat stacks on dry, level platforms. One good means of storing plywood at the job site is shown at right.

Edge protection. Where any edge or surface of the plywood is to be permanently exposed to the weather, use only Exterior-type plywood.

*from the American Plywood Association's Form No. 64-690.

21257

D.4. PLYWOOD (Reprinted from "Plywood Properties, Design and Construction" by Nelson S. Perkins, C.E. unless otherwise noted)

2. FASTENINGS

These include various devices, such as nails, staples, and glue, for attaching both plywood to framing, and other materials such as shingles to plywood. They also include plywood gussets for jointing co-planar truss or rigid frame members, and clips for aligning adjacent panels on roofs.

Most important of these several structural accessories are nails and glues.

NAILS

Nail-holding Strength. This is the capacity to resist withdrawal of nails that may be used to attach anything to plywood. This property is essential for any material serving as a base for shingles and must be adequate to hold nails firmly in place under maximum wind uplift or suction. In hurricane areas, this force may amount to as much as 25 psf and, in Southern Florida, has been estimated as high as 50 psf.

Since any type of shingle is applied with at least tow nails per sq. ft., the maximum withdrawal force in the worst storm should not exceed 25 lbs. per nail, and in most instances would be nearer 10 lbs. per nail.

Extensive testing by the U.S. Forest Products Laboratory and the American Plywood Association, as well as research at Purdue University and the Canadian Forest Products Laboratory, have served to establish plywood's nail-holding power at considerably above the maximum required in service.

21258

Annular-ring nails and screw-shank nails with a flat pitch, both types readily available, have a still higher resistance to withdrawal compared with smooth-shank nails. Such deformed nails should preferably be just long enough to have points protrude through plywood, although a minimum 1-1/8" length is needed for ease in handling; nails that are too long may cause a rasping action in plywood--thus reducing withdrawal resistance.

Tests on Sheathing and Roofing Nails. In 1952 and 1953, some 1800 nail tests were conducted by the American Plywood Association Research Laboratory to determine the best type of nail for attaching asbestos-cement shingles to 5/16" plywood sheathing. Various moisture cycles, varying from 6% to 24%, were used--thus reducing over-all average loads. Best results were obtained with a screw-shank nail, 12 gauge, 1-1/8" long, with average withdrawal load from 5/16" plywood of about 87 lbs. This nail is now recommended for use with plywood by a number of the leading asbestos-cement shingle manufacturers.

In a series of tests in 1958 at the U.S. Forest Products Laboratory*, about 700 nails were pulled from 3/8" plywood (3 plies of well randomized 1/8" D veneer) conditioned to a moisture content of approximately 12%. Withdrawal values per nail averaged about 100 lbs. with asphalt shingle nails (11 ga.), and somewhat more than 85 lbs. both with wood shingle nails (13 ga. 3d) and asbestos cement shingle nails (14 ga.) annular-ringed but 1.79" long, which is somewhat excessive for 3/8" plywood. Even when the nails were deliberately driven into knotholes in face plies, the values ranged from 37 lbs. to 98 lbs. and averaged about 58 lbs.

---

*Mechanical properties of Douglas fir plywood of "D" Grade Veneer, etc. (Limited distribution).

21259

Asphalt shingles applied to 5/16" sheathing with standard 12 gauge galvanized shingle nails, in the American Plywood Association tests, always tore away without dislodging nails; the average withdrawal load was 43 lbs. per nail.

In further American Plywood Association nail tests in 1960 for built-up roofing over 3/8" plywood, average withdrawal loads, after three cycles of 17% to 9.7% moisture content, ranged from 95 to 114 lbs. in sixty tests of annular-ring nails, and from 67 to 90 lbs. in thirty tests of screw-shank nails.

When several Western softwood plywoods were tested, withdrawal loads from 3/8" plywood sheathing ranged from 69 to 98 lbs.

It will be noted that in all these tests the average nail-holding strength of 5/16" plywood proved several times greater (4 to 10 and more*) than that needed to resist even a severe hurricane, with still higher safety factors for 3/8" and greater thicknesses.

Experience records from a number of severe hurricanes have confirmed these laboratory results. In the 1954 hurricanes, Carol and Edna, which swept Newport, R.I., with winds of 90 m.p.h., a 200-house project with asphalt shingles over 3/8" plywood roof sheathing and asbestos cement shingles on 5/16" plywood wall sheathing, survived with the loss of only two shingles on the entire project, and both of these were torn from the roofing nails.

Since then, the nail-holding power of 5/16" and 3/8" plywood under asbestos, asphalt, and wood shingles has been demonstrated during a number of similar storms, as well as by scores of case histories of less severe exposure.

---

*In Southern Florida, these safety factors might be only 3 to 5.

21260

Wood Shingles on a Tight Deck. The old question of the durability of wood shingles over a "tight" roof deck, such as plywood or T & G boards, still arises occasionally.

This matter was thoroughly investigated some 30 years ago by the National Committee on Wood Utilization*, but no evidence against the tight deck was ever uncovered. Twenty-five years' experience with plywood roof sheathing has pretty well laid this ghost to rest.

The tightness of the deck is immaterial. FHA accepts such construction under its MPS, and so does every building code, so far as is known. Although "spaced" sheathing is permitted under wood shingles, a plywood deck is better construction.

Subflooring Nails. Nail-holding strength also comes into play in a much less critical manner with plywood subflooring in the conventional 1/2" and 5/8" thicknesses, where finished flooring is applied. No particular problem arises, however, except where nails are driven into green, unseasoned joists. In such cases, the joists dry out and shrink away from the nail-head since obviously the nail will not penetrate deeper because of this. This so-called "nail popping" may cause bumps or local raised areas in thin tile flooring, but may be minimized by setting nails slightly below surface and omitting any filling. This popping has no relation to nail-holding strength of plywood, but has often been confused with it.

Why Nails Pop

*U.S. Department of Commerce

21261

Nail-Bearing Strength. In plywood this is usually a measure of the lateral bearing load that can be transmitted from the panel to the shank of a nail driven into a wood framing member. The nails are in single shear.

Important applications occur in roof sheathing, which transmits horizontal stresses (wind, earthquake, etc.) to framing, and in plywood wall sheathing, which transmits such shear forces down to the bottom plate and into the foundations. Plywood gusset plates in roof trusses, diaphragms, and nailed box beams constitute other common uses.

The strength of the nail joint in actual practice is usually governed by the bearing value of the nail against wood studs, plates, or rafters, but could be limited by the plywood if the panel were too thin or the nailing unduly heavy. Obviously, proper balance of joint details is desirable for the most economical utilization of materials.

Tests have shown that 5/16" plywood is thick enough to develop approximately the full bearing strength of 6d common nails, 3/8" for 8d common, 1/2" for 10d common, and 5/8" for 16d common nails, all driven into wood members of similar density and of adequate thickness.

A 3/8" edge-clearance is desirable for nailing plywood, as nail-bearing strength decreases rapidly with lesser margins. A 3/8" edge distance is practical and is normal for panels that butt over a 2" framing member. Results of nail-bearing tests by the American Plywood Association, where plywood was nailed with a 3/8" edge-clearance to 2" x 4" studs, showed values below:

21262

ULTIMATE NAIL BEARING LOADS

3/8" EDGE CLEARANCE

PLYWOOD THICKNESS	"COMMON" NAIL SIZE			
	6d	8d	10d	16d
5/16	275	305		
3/8	275	340		
1/2		350	425	
5/8		350	425	445
3/4			410	445

Even with loads acting perpendicular to the edge of the panel (and framing member), maximum bearing values occurred with nails about 1/2" to 3/4" from the panel edge and 1" or so from the side of the stud, and ran as much as one-third higher than those in table above. The grain direction of the plywood had no influence on the ultimate loads.

It should be noted that, when plywood walls or roofs are subjected to shearing stresses, the principal forces act parallel with the edge, making the nail location much less critical than it might otherwise be.

Casing Nails. The bearing value of these, from limited American Plywood Association tests, averages about two-thirds that for common nails having the same "d" (penny) designation.

STAPLES

Rapid-acting stapling machines, some pneumatic, others mallet-driven, have brought patented staples into use both for attaching plywood to framing, and asphalt shingles to plywood.

21263

The Research Committee of the Uniform Building Code, for example, has approved* a 16 gauge staple with 1-1/8" legs and 1/2" width as an alternate for 6d common nails, for either 5/16" or 3/8" plywood diaphragms, but has limited its shear values to 7/16 of those in the Code for plywood applied with 6d common nails.

A heavier staple, 14 gauge with 1-1/4" legs, tested by the American Plywood Association, showed values equivalent to 6d common nails in both lateral bearing tests and in full-scale diaphragm tests. T-nails and other types of mechanically applied fasteners are also available. Information on further code approvals and acceptance by FHA may be obtained from the various fastener manufacturers.

Power-driven staples used to attach shingles to plywood sheathing, in general should be of following minimum dimensions:

Wood shingles: 16 ga.; 7/16" crown; length, sufficient to penetrate bottom surface of plywood; 2 to each shingle.

Asphalt shingles: 16 ga.; 3/4" crown; 3/4" length; 2 to each shingle, or 6 for 36" section of strip shingles.

Built-up Roofing: 16 ga.; 7/16" crown; 7/8" length, driven through tin caps on 12" centers.

BOLTS

These have only limited use in plywood construction. No accurate bearing values have been established, although the American Plywood Association had a series of

---

* Research Committee Reports Nos. 1101.4 and 1101.5, 1960.

21264

tests conducted a number of years ago on 1/2" and 3/4" diameter bolts in plywood of 1/2", 5/8", and 3/4" thicknesses.

Attempts to rationalize bolt-bearing values by taking projected area of bolt against the several veneers and using allowable compression stresses for wood at applicable angle to the grain, lead to ultra-conservative results. Even if such theoretical values are doubled, factors of safety are still higher than those commonly associated with wood, i.e., 3.6 on ultimate and 1.6 on proportional limit. These presuppose adequate end-clearance of at least 3" for 1/2" bolts in 1/2" to 3/4" plywood, up to 6" for 3/4" bolts in 3/4" plywood. Edge distances should range from 1" to 3" depending on bolt size and plywood thickness.

GLUING

When glue is used to attach plywood to a wood framework, as in various structural components, cabinet work, and the like, the process is known as secondary gluing, to distinguish it from the primary gluing in manufacturing plywood itself.

Secondary gluing for structural assemblies may be of a water-resistant type or of a virtually waterproof type, depending on the anticipated exposure. In either case, the glue is designed to develop shearing stresses between the two surfaces being joined, and therefore should be stronger than the wood itself in this respect. Fortunately, excellent glues are available for such work, which includes box beams and other structural components.

Glue joints in direct tension perpendicular to the glued surfaces are comparatively weak, since at best they can be no stronger than wood in tension perpendicular to the grain.

21265

GUSSET PLATES

Plywood gusset plates constitute an effective and economical means of jointing co-planar truss members. These are also effective as bracing between columns or posts and bearing trusses or beams.

High panel shear and nail-bearing of the plywood are responsible for its success in all applications.

Gussets may be glued instead of nailed to truss members.

Gusset Plate At Heel Joint

PLYCLIPS*

These are patented H-shaped extruded structural aluminum-alloy clips 3/4" long and 1-3/16" wide. They were developed* as roof panel support in lieu of cut-in blocking, primarily for 3/4" plywood on 48" spans where two Plyclips per span are used.

---

*By Plywood Research Foundation (An American Plywood Association subsidiary), Tacoma, Washington.

These permit significant labor savings over cutting and applying blocking.

They are available in sizes for 5/16", 3/8", 1/2", 5/8", 3/4", and 13/16" plywood panels. A single Plyclip at middle of allowable plywood span is adequate edge support, except for 3/4" and 13/16" panels on 48" spans, where two equally spaced clips are recommended.

In tests at the American Plywood Association's Applied Research Laboratory, Plyclips sustained average concentrated loads of 849 lbs. with a minimum of 558 lbs. and a maximum of 1309 lbs. Loads were applied 3" back from the Plyclips placed at center of span between two butting panels nailed conventionally to framing.

Edge deflections under 250 lb. loads were reduced about 40%; differential deflection between adjacent panels was less than 1/16".

Repetitive loads of 500 cycles @ 250 lbs. showed no deteriorating effect.

Plyclips At Joint Between 3/4" Roof Panels

Plyclips were approved by the Research Committee of ICBO* in 1958. Since then some 55 million have been used, mostly in plywood roof construction.

*International Conference of Building Officials

21267

RECOMMENDED MINIMUM NAILING SCHEDULE *

Minimum edge distance of $\frac{3}{8}''$ recommended.

ywood Use	Plywood Thickness (inches)	Nail Size	Nail Type	Nail Spacing on Supports (inches)		Special Requirements
				Panel Edges	Intermediate	
of Sheathing	5/16, 3/8, 1/2 5/8, 3/4	6d 8d	Common Common	6 6	12 12	
all Sheathing	5/16, 3/8, 1/2 5/8	6d 8d	Common Common	6 6	12 12	
Subflooring	1/2 5/8, 3/4 1" 1 1/8" (2.4.1)	6d 8d 8d (or 10d com.) 8d (or 10d com.)	Common Common Deformed Shank Deformed Shank	6 6 6 6	10 10 6 6	If resilient flooring is to be applied without underlayment, set nails 1/16" and use deformed shank nails. (6d for 1/2", 5/8", and 3/4" plywood).
Diaphragms	1/4 and thicker		Common	6	12	Nail size and spacing determined by shear requirements; do not exceed spacing shown.
nderlayment	1/4, 3/8, 1/2 5/8, 3/4	3d 4d	Ring Shank	6 6	8 each way 8 each way	Nails shall have 20 annular rings per inch of shank, to within 5/16" of head. Heads shall be flat counter-sunk. Length shall be sufficient to penetrate 3/4" at least into subfloor. For plywood 1/2" and less, shank diameter shall be at least 0.080" and head diameter 3/16". For plywood 5/8" and 3/4" thick, shank diameter shall be at least 0.098" and head diameter 1/4".

21269

UNIT II - STRUCTURAL WOOD MATERIALS

4. b. PLYWOOD DIAPHRAGMS

From the standpoint of racking resistance and bracing, the conventional applications of plywood for wall and roof sheathing, and to some extent also for subflooring, have been based on knowledge of its adequacy as developed originally in a series of tests by the U.S. Forest Products Laboratory.

In the modern plywood diaphragm, however, a rigorous engineering design has replaced older empirical methods.

Definition. A diaphragm has been defined as a thin, structural element, either flat or curved and usually rectangular, capable of resisting shear parallel to its edges.

More clearly, perhaps, the Semismology Committee of the Structural Engineers Association of California defines a diaphragm as "essentially a horizontal girder, composed of a web (such as a floor or roof slab) with adequate flanges, which distributes horizontal forces to the vertical resisting elements."

History. California has the distinction, born of necessity, of fathering earthquake design methods which other areas are wisely pursuing.

21270

Flat Girder Concept of Plywood Roof Sheathing

UNIT II - STRUCTURAL WOOD MATERIALS

The San Francisco earthquake in 1906 tragically demonstrated the need for designing buildings to resist seismic as well as wind stresses. The Santa Barbara quake in 1925 stimulated research, and the Long Beach quake of 1933, with its wide destruction of buildings, many of which were masonry-walled schools (fortunately not in session), prompted immediate legislative action by which the State Office of Architecture and Construction was made responsible for approval of plans and specifications, as well as supervision of construction for all public buildings. That State Office quickly adopted design rules which, among other requirements, established lateral design loads based on weight of the building and its live load. Since then, due to extensive research and field investigations of various quakes, many refinements have been developed by structural engineering societies and their members, and have been adopted in building codes.

Out of the many studies came the concept of floors and roofs acting as plate girders, and of vertical walls acting as shear walls.

Research by Industry. Much of the design data on plywood diaphragms stems from a comprehensive research program initiated in 1949 by the American Plywood Association.

This work was facilitated by suggestions from the California Structural Engineers Association, the State Office of Architecture and Construction, Professor A. L. Miller, University of Washington, and others experienced in seismic design.

7. ANNUAL AND PROGRESSIVE INSPECTIONS. The procedures and scope of these inspections are set forth in Appendix D of Federal Aviation Regulation Part 43 and should be followed in detail. There are additional requirements listed in FAR 43.15. The regulations speak of 100-hour and annual inspections as being of identical scope; the only difference between the two is the persons authorized to perform them. Record entries you make are very important as they are the only evidence an aircraft owner has to show that he has complied with the inspection requirements of FAR 91.169 or 91.171. The following list should be helpful in reminding the AI of areas his responsibilities cover in determining that the aircraft complies with all airworthiness requirements (Ref: FAR 43.15(a.)

a. Configuration. The aircraft should conform to the aircraft specification or type certificate data sheet. When the aircraft does not conform, use the "unairworthy" procedures of FAR 43.11(a)(5).

(1) Alterations to the product may have changed some of the operating limitations.

(2) Unrecorded alterations or repairs may have been made. A remedial course of action may warrant the following:

(a) Contact owner for pertinent information.

(b) With owner's consent, wire FAA in Oklahoma for information.

(c) If approved data is available, conduct inspection and personally approve.

(d) Contact local FAA inspector for assistance.

(3) The aircraft specification or data sheet indicates when a flight manual is required. It also identifies limitations which must be displayed in the form of markings and placards.

(4) The type certificate data sheets on later models of aircraft do not contain the lists of equipment approved for a particular aircraft as did the older aircraft specifications. This list of required and optional manufacturer's approved equipment can now be found in the original equipment list furnished with the aircraft. Sometimes a later issue of the list is needed to cover recently approved items.

b. Condition. Using the checklist in FAR 43, Appendix D, the manufacturer's inspection sheets, or one of your own design, that includes the items listed in Appendix D, check the condition of the entire aircraft. This includes checks of the various systems as called for in FAR 43.15.

(1) Routine servicing is NOT a part of the annual inspection. The inspection itself is essentially a visual evaluation of the condition of the aircraft and its components and certain

After two years' exploratory tests of several variables in 1/4 scale models, a series of twenty full-scale diaphragms from 12' x 20' to 20' x 40' were tested.* These were supplemented by three tests** on 20' x 60' and 12' x 60' diaphragms at the Oregon Forest Products Research Center, Corvallis, Oregon, in cooperation with the American Plywood Association.

Full Scale Test by the American Plywood Association of Plywood Roof Diaphragm

Results. Diaphragms with blocking and nailing at all panel joints were found to be fully shear-resistant, with less deflection and greater strength than if unblocked.

Also, arrangement of panels as to staggering and continuous joints affected results. These features were all considered in the widely accepted table of shear loads approved in the Uniform Building Code. These values, however, are actually limited by the bearing value of nails in wood, and not by the recommended plywood shear stresses which are considerably higher. Note that, although blocked diaphragms may be calculated quite accurately for deflection, unblocked cannot. Nevertheless, in the tests mentioned above, both types had about the same deflection at their own design load.

---

*Full report, the American Plywood Association Laboratory Report 63-A, "1954 Horizontal Plywood Diaphragm Report," by Countryman and Colbenson.

**Report T-5, October '53 by Stillinger and Countryman, and Report T-11, 1955, by J. W. Johnson.

Importance. Plywood diaphragms have proved to be a significant improvement over former construction systems. They are of great importance because they offer a simple, logical, and economical way to engineer precisely any structure sheathed with plywood to withstand lateral loads from cyclonic winds or earthquakes. Practically no area in the United States is immune to one menace or the other.

Diaphragm Action. Most diaphragms are either horizontal or vertical, although curved or gabled roofs may also be included. With ordinary good construction practice, plywood roofs, floors, and walls all will act as diaphragms while performing their other functions. A plywood sheathed exterior wall, for example, if properly anchored, will automatically act as a "shear wall" or cantilevered diaphragm, and thus usually counteract the weakening effect of large glass areas.

Plywood Decorative Panel As Shear Wall in Home With Large Glass Areas

The plywood diaphragm concept assumes that the lateral loads from wind and earthquake, which tend to deflect or push in the walls of a building are carried by the roof, functioning as a large, horizontal girder. Such a girder has for its web the fully shear-resistant plywood sheathing, and for its flanges, which carry the flexural stresses, the long wall plates to which the sheathing is attached.

UNIT II - STRUCTURAL WOOD MATERIALS

II-C - WOOD, GLUED Laminated Timber, Plywood and other Products

GLUED LAMINATED TIMBER (NDS, WHB, TCS, Film Slides AITC, Laminating Standards WWPA, WCLIB, CRA)

INTRODUCTION

Glued laminated timber is defined in the Commercial Standard CS 253-63 as "An engineered, stress-rated product of a timber laminating plant, comprising assemblies of suitably selected and prepared wood laminations securely bonded together with adhesive. The grain of all laminations is approximately parallel longitudinally. The separate laminations shall not exceed 2" in net thickness. They may be comprised of pieces end-joined to form any length of piece placed or glued edge to edge to make wider ones of pieces bent to curved form during gluing." This differs from plywood in regard to the orientation of grain in each lamination. It is also larger in size than the smaller glued lumber products.

The use of glue to join pieces of lumber together is an ancient art. There are examples in the Egyptian tombs of wood bonded together by adhesives. However, glued laminated timber as we know it today was first used on a large scale in Europe around 1905. There is a continuing history of its use throughout Europe and in the United States to a limited extent in the years between World War I and World War II. In the years following World War II the use increased dramatically, due in part to a better understanding of its properties and use potential, followed by more economical means of production. Many of the references still in use were developed during the early days of the industry. As more was learned about making the product, some of the older concepts have given way to new ideas and techniques. For example, some of the references cited list only the plain scarf joint as a means of end jointing the individual pieces of lumber. The only criteria set forth was in the slope of the cut such as 1:10. As new techniques in maching were developed, the structural finger joint became a reality. Today most of the modern specifications equate the end joint to a performance test type criteria thus permitting the use of finger joints if the joint can qualify by physical testing.

Basically glued laminated lumber consists of two raw materials -- lumber and adhesives. The adhesive is used to bond the individual piece of lumber together in a process generally called laminating. Three distinct types of bonding operations may be performed during the laminating operation:

1. Face joint bonding: The faces of each lamination must be bonded to the faces of the adjacent laminations so that members of the desired depth can be obtained.

21277

2. End joint bonding: Since one of the advantages of glued laminated lumber is the capability of producing it in large long members, the ends of each piece of lumber must be bonded to adjacent ends of pieces in the same lamination. This is usually performed by a plain scarf joint of finger joint of specified strength.

3. Edge joint bonding: Occasionally it is necessary to make wider laminations by joining two or more pieces edge to edge in a process called edge joint bonding. This process is very seldom used in laminating, since most members consisting of laminations wider than the width of the lumber used can be manufactured by lapping the joints at least the thickness of the lamination. Edge joint bonding is used extensively however, in glued lumber products such as wide shelving.

The first process in laminating is the grading and selection of the lumber to be used. In order to obtain a good glue bond, the lumber must be surfaced to precise tolerances. Also it must be arranged in the member in the manner prescribed by the specifications. The usual procedure in a member subjected to bending loads, such as a beam, is to place the highest grade lumber in the outer laminations so that they can work more efficiently. Lower grade lumber can be used on the interior. The laminating specifications for each species have charts showing the arrangement of the various grades.

The next step is to spread a sufficient amount of adhesive on the surface to be bonded and then place the lamination in a form that has the exact curvature, (if any) desired in the finished product. When the laminations are all in place in the form, pressure is applied and maintained until the adhesive has cured.

The two types of adhesives used in laminating are dry-use adhesives and wet-use adhesives.

(a) Dry-use adhesive: A water resistant adhesive designed primarily for dry use conditions. These adhesives are of the casein type and although termed dry-use they have a fair degree of water resistance and can withstand the exposure normally experienced in erecting the timbers. They should not be used where the equilibrium moisture content of the wood exceeds 16%.

(b) Wet-use adhesive: These adhesives are designed to withstand any condition of use including dry-use and wet-use where the timbers are saturated. (See TCS AITC 103-65 Section 5)

A certain amount of heat is necessary to cure the adhesives. The caseins will cure at any temperature above freezing, but higher temperatures decrease the time for which the members must remain clamped under pressure in the forms. The wet-use adhesives will cure at temperatures ranging from 70% F

21278

The moisture content of glued laminated timbers will change as the humidity and temperature of the surrounding atmosphere changes. Due to the relatively large mass to surface area ratio, the overall change in moisture content will take place rather slowly. However, if the glued laminated timbers are subject to extreme conditions of low humidity and high temperature, the wood on the surface will dry faster than that in the interior and cause some surface checking. For this reason, care should be taken to see that hot dry air is not directed against glued laminated timbers as is sometimes the case when the building is heated to dry it out prior to occupancy.

MECHANICAL PROPERTIES

The following mechanical properties are those most often used in design. The notations enclosed in quotation marks are the newer notations gradually coming into use by the industry. The notations enclosed in parenthesis are the older notations still found in many references.

"F_b" - Allowable units stress for extreme fiber in bending ("f")

"F_v"- Allowable Horizontal shear stress (H)

"F_c" - Allowable unit stress in compressions parallel to grain (c)

"F_{c1}"- Allowable unit stress in compression perpendicular to grain (c1)

"F_r" - Allowable unit radial stresses

"E" - Modulus of elasticity (a measure of stiffness) (E)

The mechanical properties of glued laminated wood which are taken into account in design are essentially those which are used in solid sawn lumber. However, in bending of the laminations to produce a curved member, some account must be taken for the effect of bending. Also, in curved beams the effect of the radial stresses induced by bending or stensile stresses at right angles to the grain of the wood can affect the design.

Basically the allowable stresses for glued laminated timber are greater than for comparable grade of solid sawn lumber for the following reasons:

1. There is a natural dispersion of knots which tends to prevent the accumulation of strength reducing characteristics at a single cross section as can happen when a single knot occupies a large portion of the cross section of a solid sawn piece.

21281

The deflection of a plywood diaphragm, as extensive research has demonstrated, can be accurately calculated, and consequently such diaphragms can be designed with sufficient stiffness to keep the horizontal deflection of the walls within recognized safe limits*.

Reactions for the horizontal diaphragm are the end walls and any partitions parallel with them. These walls are vertical diaphragms which act as cantilevers, since they receive the horizontal forces from the girder along their top plates. This stresses the end walls in shear, and consequently they are known as "shear walls." They must be properly anchored at base to resist both shear and overturning moments, and to transmit forces to the ground.

It will be noted, from previous discussion of mechanical properties, that plywood can function effectively as a shear wall and as a diaphragm web because of its high panel-shear strength and nail-bearing values.

Uses. Plywood wall, roof, and floor diaphragms are used most commonly in wood frame buildings. Plywood roofs and floors as well as interior partitions are frequently used as diaphragms in masonry or concrete walled buildings. In earthquake areas such as California, plywood roof diaphragms in one-story industrial buildings and in schools have virtually displaced other materials. Plywood sheathing, although customarily used in combination with wood joists has also been employed successfully as horizontal diaphragms with steel joists.

Churches, auditoriums, warehouses, and commercial buildings, ranging in size up to at least 500,000 sq. ft., have utilized plywood diaphragms successfully.

PHYSICAL PROPERTIES

The physical properties of glued laminated timber are essentially the same as the species used in manufacturing the timber. The adhesive has a relatively minor effect on the basic physical properties of the wood. The main difference between solid sawn timber and glued laminated timber is in the moisture content and shrinkage. Glued laminated timbers are manufactured with dry lumber, and the amount of shrinkage and checking due to change of moisture content is considerably less than solid sawn timbers.

21280

AMERICAN PLYWOOD ASSOCIATION FILMS

Available from Film Library, Information Services Division, American Plywood Association, Tacoma, Washington. Booking requests should also include an alternate date, in the event a film is not available for the date requested.

1. Miracle in Wood (16 mm, color, sound, 27 minutes)
   An entirely new version of an earlier film with the same name. Traces early history of veneering up to what we know as plywood. Covers logging phase briefly and shows manufacturing. Balance is devoted to plywood uses. (Each Regional Office has a print.)

2. Design Versus Nature's Violence (16 mm, black and white, sound, 18 minutes)
   Report on how various types of construction survived the 1964 Alaska earthquake. This film also explains plywood's diaphragm advantages for hurricanes as well. (Each Regional Office has a print.)

3. Tamap Roof Sheathing Study (16 mm, color, sound, 26 Minutes)
   Documents highlights of "time and motion" study on plywood roof sheathing conducted by National Association of Home Builders Research Foundation. Intended for builder, architect, engineer audiences.

4. Olympic Village USA (16 mm, color, sound, 14½ minutes)
   Film report on site preparations for the 1960 Winter Olympics... how Squaw Valley, California, was transformed from a peaceful meadow into an Olympic site in record time. Construction and planning of sport facilities and related structures illustrated. Unique construction methods and softwood plywood products combined to finish job on schedule.

AMERICAN PLYWOOD ASSOCIATION SPEAKERS

Speakers are available from the American Plywood Association. Arrangements should be made with either the Los Angeles Regional Office (9845 McNerney, South Gate, California) or the San Francisco Regional Office (3030 Bridgeway, Sausalito, California) at least two months prior to speaking engagement. Plywood Association speakers will make folders of appropriate literature available to class.

"PLYWOOD PROPERTIES, DESIGN AND CONSTRUCTION" by Nelson S. Perkins is available from the American Plywood Association at a cost of $2.00 per copy. Reduced rates are available to local book stores.

21276

to 300° F depending upon the type and brand of the adhesive. In all cases however, the curing temperature should be in accordance with the adhesive manufacturer's recommendations.

After the adhesive has set, the sides of the timbers are planed smooth and usually some additional fabrication such as triming, cutting of slopes etc., is performed as may be required by the plans.

Arches and other curved members are checked during the fabrication to make sure they comply with the plans and specifications. For this purpose the same template that was used to set the forms is used to cut the member to the correct shape supplemented by checks of key dimensions. Most beams are manufactured with a slight curvature called camber to offset the deflection or sag in the beam caused by the dead load of the building. This camber should be in accordance with the plans and specifications. (See reference TCS AITC 102 65 Par. 9.8 and appendix B.) In erection it is important that the beams are placed in an upright position and not turned over so that the "cambered" beam does not sag. End sealers and surface sealers are often specified since they offer a degree of protection to the member.

(b) AITC 103-65 Appendix A-Selection of Adhesives.)

21279

Horizontal plywood diaphragms are particularly suitable where appearance of the exposed smooth undersurface is important. Plywood in shear walls or partitions may serve as interior finish while also performing its diaphragm function. Diaphragms are frequently used also to carry gravity loads, as in the case of folded plate roof construction, discussed in the next chapter.

21275

operational checks. The manufacturer may recommend certain services to be performed at various operating intervals. These can often conveniently be done at this time, and in fact should be, but should not be considered as being the inspection itself.

(2) It is very important to be familiar with the service manuals, bulletins, letters, etc., for the product being inspected. It makes good sense to utilize the experience other people have had on similar products, so use these publications to avoid overlooking problem areas which might not otherwise come to your attention.

(3) The FAA General Aviation Inspection Aids are also a source of service experience available to you. These Aids are summaries of difficulties reported to FAA on FAA Form 1226, Malfunction or Defect Report.

(4) At the time he certifies the inspection for an aircraft as airworthy, the AI will be held responsible for condition of the aircraft AS OF THE TIME OF THAT CERTIFICATION.

c. Airworthiness Directives. The AI should make it a point to see whether all applicable airworthiness directives have actually been complied with on the aircraft, the powerplant, propeller, instruments, and appliances.

(1) If the maintenance records indicate compliance with an AD, the AI should make a reasonable attempt to verify this. He would not be expected to disassemble major components such as cylinders or crankcases, etc. The reason for this being that it is not uncommon for a component to have an AD complied with and properly recorded and then later be replaced by another on which the AD had not yet been accomplished.

(2) When the records do NOT contain indications of previous compliance, the AI should do whatever disassembly is necessary to verify the actual condition.

(3) Often an AD calls for an inspection at one time with a modification required at a later date. On these it is very important to identify the portion of the AD complied with and the exact method of compliance.

(4) Section 91.173(b)(2) of the FAR requires an owner to keep a chronological listing of compliance with service bulletins, and airworthiness directives, and the method of compliance. As a vital part of the services an AI performs, he can provide the information the owner is expected to keep.

MICROCOPY RESOLUTION
NATIONAL BUREAU OF STA

N TEST CHART

NDARDS-1963-A

2. There is less chance for hidden imperfections to be present in glued laminated timber since the use of relatively thin pieces permits a visual inspection of most of the wood substance contained in the member.

3. Glued laminated timbers are required to be manufactured from dry lumber. Full advantage can be taken of the increase in strength for dryness. In bending, for instance, dry lumber is 25% stronger than green lumber. When glued laminated timbers are used in wet locations where the fibers become saturated, this increase in strength for dryness does not apply.

4. The adhesive used in laminated timbers is capable of bonding the wood together in side grain bond in a joint that is as strong if not stronger than the wood itself in the mechanical properties essential to developing the strength of the wood. Therefore, it is possible to consider glued laminated timbers as one solid mass of wood, the strength of which depends on the strength of the wood. The allowable stresses of glued laminated timbers as shown in the laminating specifications were determined by making an extensive study and analysis of each species used, which included the basic stress of the species, the effect of allowable knots permitted and the probability of dispersion of the knots through the member, the effect of slope of grain and the strength of the end joint that is needed. Such studies have been made on most of the important commercial species and laminating specifications for each have been prepared. The references at the end of this section contain the laminating specifications generally used in Commercial production.

When adhesives are used to join wood, end grain to end grain, the resulting joint is not as strong in tension as the wood. Therefore, either a plain scarf joint or a finger joint is used to increase the area of gluing. Such joints develop a large percentage of the strength of clear wood. The strength of the end joint is taken into account in setting the allowable stresses of combinations used in laminating. Many of the references cited include only the plain scarf joint of a specified slope such as 1:10 as the only criteria for end joints. The more modern specifications include a performance test (See TCS-AITC 103-65) which allows the use of finger joints as well as plain scarf joints.

The references included at the end of this section list the allowable stresses for the most important species used in laminating.

The allowable strength properties for each combination of each species are listed. Since most members used are flexual members, the allowable fiber stress in bending quite often controls. This stress varies as the grade of the lumber in the combination varies, also the allowable compression parallel to grain varies with the grade of the laminations, compression perpendicular to grain varies only as the density of the

wood varies, horizontal shear and modulus of elasticity vary very little with grade and are considered to be the same for all combinations of a given species. It is interesting to note that on long span beams (particularly those used on flat roofs), the deflection may control the design instead of bending strength. In which case a combination with a lower allowable fiber stress in bending may be specified. For instance, where deflection controls a combination with an allowable fiber stress in bending of 2400 or 2200 psi may be used rather than a 2600 "f" combination.

Glued laminated timbers are quite often relatively large and deep compared to solid sawn timbers. For this reason the effect of depth must be taken into account when determining the allowable fiber stress in bending used in design. (See appendix D NDS). This factor is taken into account in the design of glued laminated timbers and is usually of no concern as far as the erection and inspection is concerned. It is interesting to note however, that the allowable fiber stress in bending of a beam 32" deep is only 85% of that of a similar beam 12" deep.

UNIT II - STRUCTURAL WOOD MATERIALS

II-D - STRUCTURAL USE OF WOOD PRODUCTS

BASIC ENGINEERING AND CONSTRUCTION PRINCIPLES

(A) INTRODUCTION

This section is intended to cover the use of wood in Structures where the sizes, shapes, placement and fastenings of wood members have been determined on a rational basis by engineering design. It is beyond the scope and purpose of this section to include the design of structural wood members, however it is felt that the basic principles involved should be discussed in order to develop a better understanding of the reasons behind the design of the structure.

In small buildings such as residences etc., much of the design is done by the use of tabular information such as selection of the species and size of floor joists rafters, ceiling joists, studs nailing patterns, etc., from charts or tables. In many cases the nailing pattern is not specifically shown on plans and is left up to the carpenter to use standard nailing practices. However, in larger structures the loads and forces involved in design require that each part of the building be analyzed by engineering methods to determine the size of each member and the design of fastenings for the structural system. In which case the sizes, spacing and details of fastenings are included in the building plans.

Wood as a structural material is subject to the same laws of engineering and physics as other materials. The load carrying capacity of wood varies with species and grade. Allowable stresses have been devised for all important commercial species of wood so that the designer can proportion the material to carry the loads to which it may be subjected. Although the basic laws of physics apply to lumbers, it is unique in some of its strength properties and certain adjustments to the general rule are used in design.

For these reasons adjustments are made for duration of load, moisture content, and deflections.

Design information concerning these and other aspects of wood design and construction are contained in the following references.

(5) The owner should also be informed if there are subsequent requirements of an AD or that some may require reinspection at certain operating intervals other than at annual inspections. Often these are at 100-hour intervals and will be due whether or not the aircraft is legally required to have 100-hour inspections.

(6) To assist an AI in keeping his reference material current, we recommend that he add the new ADs to the space provided in the index of the AD summary.

d. AIs are encouraged to report all malfunctions or defects that come to their attention. Report forms, FAA Form 1226, are available from all FAA district offices, are easy to fill out, and need no postage. See Figure 4. Prompt reporting will contribute much toward improving air safety by helping correct unsafe conditions.

e. Paperwork Review. The owner/operator is responsible for maintaining the equipment list, center of gravity, weight distribution, and loading schedules if necessary.

(1) The AI should determine that the placards and documents set forth in the aircraft specification or data sheet are available and current. The aircraft is not to be reported as "unairworthy" if these placards and documents are not available, but the owner/operator should be informed that under FAR 91.31 the aircraft should not be operated until they are available.

(2) The AI should refer to the registration and airworthiness certificates for the owner's name and address and for the aircraft make, model, registration, and serial numbers needed for reporting purposes. Be sure not to use the manufacturer's trade names as these do not always coincide with the actual model designation (Cessna Skyland is 182, Piper Comanche is PA-24-250, etc.). Here again, if these certificates are not available, the aircraft is not to be reported as unairworthy. The owner/operator should be informed that the documents must be in the aircraft with the airworthiness certificate displayed as required in FAR 91.27 WHEN THE AIRCRAFT IS OPERATED.

(3) Other documents often needed but not a part of the airworthiness requirements might be state registration, FCC radio station licenses, etc. The owner/operator is responsible for the proper display of these documents. However, the AI will be performing an appreciated service when he informs the operator of any deficiencies in the display and carriage of these documents.

UNIT III - STRUCTURAL METALS

Objective

The objective of this unit is to familiarize the student with the physical properties of structural metals, the shapes available for building construction, identification of metals and shapes, and how metals are used in building construction. Most of the course time will be spent on interpretation of construction drawings, study of welded and bolted connections, and analysis of field problems.

First Session

A. Introduction (One Hour)

The introductory period is intended to broadly cover the entire field and the use of structural metals in building construction. This might be formally divided between aluminum and steel or treated by function within the building.

A group of slides depicting buildings during construction can be used to begin the period. A representative selection of slides featuring member types, connections, and overall building views often are available through the local AISC representative and can be supplemented with similar slides obtainable from the Aluminum Association. The industry representatives usually are willing to present the slides with appropriate comments.

Following the slides, a general outline of the content of the structural metals portion of the course should be presented. The outline should lightly touch upon those topics of importance to the inspector that will be covered in detail in subsequent sessions.

STRUCTURAL STEEL INSPECTION

A. A. Anderson

INTRODUCTION

Any job with structural steel requires a steel inspector and he can be from a testing lab or hired directly by the owner from an approved list, or from the Department of Building and Safety. Where the steel is not to be stressed over a low percentage of its capability, some testing and inspection is usually waived. Structural steel is particularly important because of the high allowable stresses used by the Structural Engineer in his design where each member is required to carry this stress safely. The steel members, columns, beams, or tapered steel girders are the structural members upon which the rest of the building depends and it is not hard to understand why so much emphasis is placed upon proper design, fabrication, erection, and inspection. Connections from one member to another are the means whereby the strength of the steel is transmitted eventually to the foundation and the structure is no stronger than its connecting elements. Welding is being used more and more to make these connections and more and more emphasis is being placed on proper welding.

ELECTRODES

Title 21 of the State of California Administrative Code of Public Works sets up certain construction procedures and regulations that school districts must follow. Local, Federal, and other governmental agencies also have regulations that follow in most respects the American Institute of Steel Construction recommendations. Certain rigid qualifications must be adhered to in inspection and the inspector shall be trained and experienced in inspecting welds on work requiring unquestioned reliability. First, the basic steel used must meet A.S.T.M. specifications and be sampled, tested, and approved. The welders must have demonstrated their ability to produce sound welds. Also, the welding electrodes must meet qualification or specifications. Because the electrode is an important part in making the connection, I would like to discuss various aspects of electrodes and some newer electrodes that are becoming generally used. Technically an electrode is a filler metal in the form of a wire or rod which is used as a terminal in an electric current to produce an electric arc.

General Electrode Classifications. There are many types of electrodes and they may be classed in many respects, for instance, as to the kind of material, either metallic or carbon. Or as to the coating whether a real light or wash coating is used or a heavy coating or perhaps something in between. The metallic electrode may be mild steel, low alloy steel, manganese steel, or another alloy. Other classifications include these with respect to current, DC or AC, or respect to size or polarity. The usual el ctrodes range in size from 3/32 to 3/8 inch in diameter and are from 9 to 18 inches long. For our use, however, we are concerned primarily with the American Welding Society classification of heavy coated shielded arc electrodes.

is to use an old refrigerator with a light bulb left on continually for heat. On the job the welder must keep these rods dry. We require that they have a method of keeping the rods warm and that only a few rods be taken out of this hot-box at a time. Also the welding heat or amperage is higher for the low-hydrogen electrodes, so it is important that the welder demonstrate proficiency in its use. Used properly with the right heat, the weld is practically self-slaging. This is also a method of checking on the welder. If he is having difficulty in slaging,he is not welding properly with the low-hi rod. The advantages of the low-hi electrodes lie primarily in their ability to weld the difficult to weld steels such as higher carbon or high sulfer steels. It is proper to use low-hydrogen when the carbon content is unknown, such as in welding bolts or connections to existing structural elements. It is necessary to use them when welding reinforcing bars. Again the low-hydrogen electrode is the equivalent of E6010 in strength and is superior in welding higher carbon steels and leaves a much smoother shinier weld, and once the welder learns the knack of using it he usually prefers to use it. Indeed a great number of field welders carry only low-hydrogen rods because of their all purpose qualities.

Newer low-hydrogen electrodes, as well as others, have iron-powder as part of their coatings. This iron-powder melts with the coating in the arc and forms part of the weld, making a smoother and faster weld. Another new development is the classification of a single electrode in the E70 series as well as in the E60 series so that the same one is qualified for both 60,000 psi and 70,000 psi welds.

POWER REQUIREMENTS

The arc welding process requires a continuous supply of current sufficient in amount (amps) and of proper voltage to maintain the arc. The current may be either alternating or direct, but it must be provided through a source which can be controlled to meet the variables of arc welding. The voltage will range from 17 to 45 volts and the current will range between 10 to 500 amps. In automatic welding, the amperage can go as high as 1500. Alternating current is produced in special welding transformers designed so that they respond to the varying demands for current. Direct current is produced by either rectifier sets or motor driven generators. Combination welders producing both AC and DC are basically transformer-rectifier sets. A rectifier is a metal (selenium or silicon) which allows the current to pass through in only one direction thereby changing AC to DC. On the job site a gasoline motor driven generator mounted on a truck provides the DC used in the field welding. The utility lines are a cheaper power source therefore the shops use either electric motor driven generators or transformers. However, all welding machines must be able to vary the voltage and current to meet the constantly changing demands as the length of the arc changes or when starting the arc. They are provided, also, with suitable manual controls to regulate the speed and to adjust the operating amperage or heat. Most machines have controls for regulating the heat but because of the delicate mechanism required and the rough usage they get, the only sure indication of the proper heat is in the welding itself. The welder and the inspector can tell by the puddle and the weld whether the heat is right or not and also by the sound if the welding is being done properly in most cases.

Number Coding. The A.W.S. designation is a series of four or five digit numbers prefixed with the letter E (indicating electric welding or electrode). The two numerals following the letter E multiplied by 1000 predicts the minimum tensile strength of the deposited metal. The next digit indicates the best welding position of the rod and the last number covers other information, such as coating, polarity, or presence of iron-powder in the coating. For instance, take the E6012 red. We know by this number E6012 that the weld will develop 60,000 psi tensile strength. It can be used in all positions - flat, horizontal, or overhead, as indicated by the number one. If the number two had been the next to the last number such as E6024, we would know the rod is recommended only for horizontal or flat welding. Number three limits the rod to a flat position. These position numbers actually show the rate of solidification of the weld metal. The number one rod quickly solidifies or freezes as would be required for an overhead weld. Number three flows easily and is best suited for a flat weld where the sides of the groove help restrain the molton metal. The last number in the example E6012, the number 2 tells us that the electrode is preferably used with an AC machine, has a medium digging arc, and has from 0-10% iron-powder in the casting. These qualities are practically the same regardless of the manufacturer. The most important information is in the first three numbers, that the deposit metal will be in the right range and used properly.

Color Coding. There are many other properties of welding rods classified by A.W.S. Because most of our structural steel is low carbon steel having a tensile strength between 60,000 psi to 75,000 psi in the case of A7 steel and up to 80,000 psi for A36 steel the electrode must have the same properties as the base metal, so our principle concern is with the E60 and E70 series, heavy coated shielded arc electrodes. A color coding system for the purpose of readily identifying the electrode is furnished. The inspector should be familiar with this system. We are concerned primarily with the color on the bare end of the electrode that is attached to the holder and the spot color located on the uncoated section. Absence of a color on the end tells us the electrode is in the 60,000 tensile strength series. A blue or black end indicates an E70 electrode . Then the individual A.W.S. classification is defined by the color spot located on the bare, uncoated section. No colored spot means the electrode is 6010, a blue spot means 6011, a white spot means 6012, and so on. This system also allows manufacturers to stamp identification numbers on the rod coating. Now most manufacturers are doing this, stamping the A.W.S. number right on the coating of the larger rods thereby making it easier to identify for the inspector as well as the welder.

Electrode Coating. The quality of the weld metal is affected to a marked degree by the coating on the electrode. Before the advent of the coated electrode, a bare rod was used; but this left the molten weld unprotected from the surrounding air and did not concentrate or direct the electric arc, so it is really the development of the coating that has brought welding into prominence. This coating causes a more stable arc, smoother weld beads, and improves the quality of the weld by protecting the liquid metal from the gases in the air - oxygen,

The above is a typical FAA Form 1226, Malfunction or Defect Report. AIs are urged to use this form for all malfunctions or defects that cannot be attributed to poor maintenance procedures. AIs are requested to be accurate in completing the blocks on the face of the form. It is not necessary to furnish models and serial numbers when they are not pertinent. Note that there is a recommendation as to how the defect can be corrected.

nitrogen, and hydrogen, which, if allowed to combine with the molten weld would reduce its tensile strength and ductility. This ductility is very important. It is that ability of the weld, as well as of steel itself, that allows the stress to be uniformly spread out over the entire section by the plastic giving or flow until all surfaces are bearing. Anyway, these harmful gases are prevented from reaching the weld until it has solidified by an inert gas envelope and the coat of slag both caused by the burning of the coating in the electric arc. The coating is usually organic or metallic depending upon what characteristics are desired in the arc. An organic coating such as cellulose usually cotton fibers provides a carbon monoxide gas which protects a deep digging penetrating arc while the metallic coatings induce a softer and less penetrating arc. The mineral types produce slag only while it takes the cellulose to form the gas shield. The residue from the burned coating forms the slag on the weld surface which also serves to protect the weld, as I have said.

Welding Technique. Basically, the lower the number of the electrode the more penetrating the arc and the faster the solidification. The E6010 electrode is an all position rod that produces excellent welds in mild steel. It is the primary field rod used because of these qualities and because it performs best on direct current such as a gasoline driven motor generator mounted on a truck would provide. The counterpart in the shop is E6011 having much the same characteristics but operating best on alternating current furnished by a transformer. Because the shop has the facilities, many different rods are used primarily because of economic reasons. If a weld can be positioned to a flat position, a larger electrode can be used and a more fluid type can be used thereby making it faster and easier to make the weld. There is very seldom an overhead weld in the shop, for example, as you would find on the job. These mud rods such as the E6024 make an acceptable weld in most cases but should be avoided on butt weld splices because they make a more brittle weld than the E6010 or E6012, and the butt weld must transmit these forces that require more ductility. The technique of welding with this rod is to drag it over the area with the coating just touching. This makes the weld relatively easy to make which is a great advantage. Also, it makes a very good appearance compared to the definite ripples made by the E6010. The drag technique makes holding a short stable arc much easier and holding the arc so that it penetrates or digs into the base metal is very important. The digging action of the arc is much more apparent in the E6010. Here the welder holds the molten puddle behind the short arc as it moves along being sure that the arc at all times is digging into the base metal and not wasting energy over the liquid metal itself. The maintaining of a uniform arc is also very important. To make a sound weld it is necessary that the metal deposited from the electrode fuse completely with the base metal. This can be done only when the base metal has been heated to a liquid condition and the electrode metal flowing into it is also liquid. The length of the arc determines how liquid these metals are. If the arc is too short, it causes the electrode to stick frequently and is hard to manipulate and also fails to create enough heat to form the crater of molten base metal. If the

21299

arc is too long, the metal drops off in large globules and the heat is not localized enough to form the molten puddle thus also producing poor fusion of the steel. The correct length of the arc is about equal to the diameter of the core wire of the electrode being used.

Current and Polarity. Some of these electrodes are best for direct current and some for alternating current. Some direct current electrodes are best for straight polarity and some are best for reverse polarity. In straight polarity the electrode is negative and the work is positive; in reversed polarity the electrode is positive and the work is negative. In other words, the condition of the electrode determines the polarity. The welding machine will either have a switch for polarity or the leads will have to be reversed to change the polarity. I try to remember it in this way, the symbol for negative is a straight line, therefore, if the electrode is negative when used, it is in straight polarity. And, if the electrode is positive or plus, it must be in reverse polarity.

Special Electrodes. An increasingly popular stick is the low-hydrogen electrode. This is an all purpose r d originally developed for welding higher strength, high carbon steels where the other types of electrodes produced underbead cracking. This cracking occurs in the base metal just under the fusion zone due to the hydrogen in the air entering into the weld. The name comes from the fact that their coating contains very little hydrogen forming chemicals. These electrodes are designed to operate with direct current, reverse polarity or alternating current with the exception of the E6015 which operates only on direct current, reverse polarity. The AC, DC, types E6016, E6018 have better usability characteristics and can be used on AC especially where magnetic arc blow is encountered. When using DC machines, a curious action of the arc sometimes occurs. This is called arc blow, indicated by a wild arc action and fingernailing of the electrode, that is, uneven burning of rod coating. Arc blow causes very poor welds in appearance and quality and is caused by the current returning to the welding machine taking an indirect course. Moving the grounding clamp will help and so, sometimes, will backstepping the weld. This is, of course, not encountered in AC due to the constantly reversing action of the current. The low-hydrogen types are generally accepted as being superior in weld metal quality when applied correctly, but the possibility of a welder making a poor application with improper techniques are greater than with the conventional types. The welding technique required by low-hydrogen electrodes is somewhat different because of the quick decomposition of the special coating forming the carbon dioxide gas. Since it takes only a fraction of a second for the electrode covering to reach the decomposition temperature when the arc is struck, a close arc must be held and a molten puddle established before proceeding with the weld. For this reason, the low-hydrogen rod is more prone to develop starting porosity or gas bubbles frozen in the weld itself, than the other types. Moisture in the coating of the low-hydrogen electrode is more harmful in its effect on the weld than in other electrodes. Although all electrodes must be kept dry to be used properly, it is more important to have a new unopened box of low-hydrogen electrodes when starting if there is any question as to whether they have been exposed to damp weather or left unprotected overnight. A good method of storing electrodes

MACHINE WELDING

Another of the changes coming about is the use of more and more semi-automatic and automatic welding because it reduces fabrication time, cuts costs, and improves weld quality. It involves the continuous wire process. Every day more and more welding is done by this method. Yet the stick or rod is used more than ever but the continuous welding is growing at a much faster rate. There are basically four processes: The submerged arc with granular flux, gas-shielded solid wire, gas-shielded flux-cored wire, and gasless flux-cored wire. All of them are either completely automatic or semi-automatic. In the welding of mild steel, either A7 or A36, the gas shielded solid wire process commonly known as CO_2 welding is used. This CO_2 process using a very small diameter wire is the only mechanized welding that can be used for out-of-position welding. The advantage here is, of course, the higher speed of welding and the increased heat or amps used makes complete penetration more positive, and since only about 60% to 70% of the stick electrode is actually deposited as weld metal whereas almost 100% of the wire becomes the actual weld, the savings in material is important. Continuous wire welding is about three times as fast. The mechanical operation makes it easier to obtain complete penetration with less skill required of the operator. The function of the semi-automatic welder is simply the automatic control of the wire electrode feed. When the operator strikes an arc, the wire starts to feed. In another semi-automatic process the welder holds a cone containing granular flux in his hand with a continuous wire electrode protruding from the pointed end of the gun. The bare wire is automatically fed by a motor on the spool at the rate of speed set by the welder. The specifications for this wire electrode are the same as for 6010 or 7010 without the coating and are as set forth in the A.I.S.C. manual. The flux pours out of the funnel on and over the weld continuously as the weld progresses. Actually continuous wire is now available in any classification found in the stick electrodes. The A.W.S. classifies, for example, a continuous wire equivalent of E7018 (a low-hydrogen rod) as E70S-J. The equivalent of E6024 is E60T-4. The S means the wire is solid while the T means tubular for the flux-cored wire. In the automatic welding process the work is usually positioned in a frame and the machine moves along the work when welding fillets on a tapered girder, for example, although sometimes the work does move through a stationary welding machine. This submerged arc welding with a bare metal electrode underneath a blanket of granular flux permits much higher speeds in welding because the arc and the molten metal are completely covered until the weld is cool. Much higher currents can be used. The arc itself is not visible being hidden beneath a heap of loose flux. The flux serves the same purpose as the coating on an electrode. The flux does not, however, form a gas but rather the flux adjacent to the arc melts, floats on the surface of the molten weld and then solidifies to form the slag. This slag is very easy to remove and in most cases it will crack off by itself as it cools, of course, some of these automatic processes using gas only leave no slag at all. The inspection required on automatic welding is to be sure that the plates are cut properly, cleaned and closely fitted before welding and also in the case of gas-shielded only that no breeze is blowing the gas shield away from the weld. The most common defect is porosity of the weld due to improper cleaning of the plates. More than a very few small pin holes on the surface of the weld is cause for rejection because many porous sections are probably hidden underneath.

example, the use of Nelson studs would be specified. The welding symbol is the language of the trade. So that everyone will know what kind of weld is required, a standard system is used. Basically, there are only four types of welds:

1. A bead weld or stringer bead
2. A fillet weld
3. A plug or slot weld
4. The butt weld or groove weld

In this last group we find the various ways of preparing the pieces to be joined depending on the thickness of the material and the weld is described or defined by this preparation:

a. The square butt weld is used only in a flat position and where the material is not over 5/16 inch thick. No beveling is done to either edge, but a gap between the pieces must be maintained.
b. The various methods of beveling the thicker peices to allow the weld to completely penetrate the joint describe the shaping to be done. Some of them are:

    1. single vee
    2. single bevel
    3. double vee
    4. double bevel
    5. single U or J
    6. double U or J
    7. flared vee
    8. flared bevel

All of these are described fully in the A.I.S.C. manual available at the Technical Book Store for $7.00. In inspecting these welds the preparation must be checked not only for shape but for the root opening called out in the welding symbol.

DUTIES OF WELDING INSPECTOR

The welding inspector must list all structural welders and can require them to make an identification mark on each of their welds. He must assure himself that all welds are sound. He may choose to test any weld by means of x-ray, magnetic flux, dye penetrant or any other method. Perhaps a cut through the weld will be sufficient to show penetration or porosity or slag. The inspector is required to inspect each weld layer, therefore, he must be present at multipass welding. Single pass welding can be inspected after welding if the fit-up and the welder have been checked out ahead of time. Any manual fillet welds over 1/4 inch shall be multiple pass welds. The inspector on school projects furnishes the architect, structural engineer and the Office of Architecture and Construction with a verified report that the welding and fabrication conform with the plans and specifications and that he has used all means necessary to determine this. The inspector should have in his possession:

1. A.I.S.C. Manual, The Sixth Edition Issued in 1963
2. A.W.S. Standard Code of Arc and Gas Welding

3. A.W.S. Standard Welding Symbols
4. A.W.S.-A.S.T.M. Specification for Electrodes
5. Title 21--This is the basic law on school construction. Article 8 of Title 21 concerns structural steel while Article 9 deals with Light Steel Construction.
6. Circular 6 from the State. This circular sets forth certain requirements for steel fabrication. The method of qualification of welders, for example, the requirements for submerged-arc welding and the welding of reinforcing bars.

His equipment includes:

1. Welders hood or hand viewer
2. Slag hammer
3. Welding gauges
4. Identification stamp

Before each welder begins, the inspector looks at each license, notes the type and position the welder is qualified for and the expiration date of the license, turns it over and checks the picture on the back. He also checks each welder's work making sure the approved electrode is used and the weld is proper.

The welder proceeds to weld using shop procedure unless otherwise directed. By this, I mean some shops prefer certain electrodes and differing procedures; but unless they affect the quality of the weld there is no reason to object. Most of the fabrication shops in our area have been licensed by the City of Los Angeles, Department of Building and Safety to be able to perform structural welding without constant inspection. The shop is always subject to periodic inspection by the Building and Safety Department at any time, however. The inspector's most important task is to inspect the welding. Most other items can be checked afterwards, but a multipass weld may be defective and only by inspection during welding can the inspector be sure that the weld is sound. The inspector watches the weld through his shield while the welder is welding. The arc must be digging into the base metal and not over the puddle. Each successive pass must be deslaged and brushed and examined for defects. As in the inspection during welding, certain signs will reveal considerable information after the welding is done. Items to consider include size and shape of the bead, appearance of the slag, undercut, overlap, location of craters (indicating where the welder started and stopped welding).

COMMON WELDING DEFECTS

Most common defects of welds are excessive concavity or convexity in fillet welds and these can be corrected by either adding more passes or grinding off the excess, undercut which is caused by too long an arc, incorrect electrode angle, excessive heat, or too rapid an arc motion, or insufficient size, either of which can be corrected with additional passes, overlap, a protrusion of weld metal over the base plate, a defect indicating poor penetration because of low heat or arc traveling too slowly.

UNIT III - STRUCTURAL METALS

QUALIFICATION OF WELDERS

The welder must be certified by some public authority as to having passed tests proving his ability to weld satisfactorily. Manual welding procedures and welder qualifications for structural steel, that is, (3/16 inch or over in thickness) are as prescribed in the "Standard Code for Arc and Gas Welding in Building Construction" of the American Welding Society. Incidentally, gas welding is not used for structural welding because of many reasons. Most important is its lower strength due to lower welding temperature and its relatively more difficult welding technique and consequent loss of reliability. The gas company, however, conducts classes in gas welding for its employees on their pipe lines and has found it satisfactory. In our work the welder, in order to be certified, must have passed rigid tests of his ability to perform the quality of welding required by the designed strength of materials. The welder must be qualified to perform the type of welding to be done. In the case of the automatic weld, the operator may be checked by testing some of his work using the same equipment that he will use for production. Welders shall be checked by the welding inspector, and those not doing satisfactory work can be removed and be required to pass the qualification tests again.

In this area certification by the Los Angeles Department of Building and Safety is accepted. The types of licenses issued are Structural Steel-Shop, Structural Steel-Shop and Field, Lightgage Steel-Shop and Field, and Aluminum Shop and Field. The applicant must first pass an oral examination on electrode identification, that is be able to identify the electrode number by the color code, know the approved welding position and polarity. He must be able to read welding symbols and answer questions on procedures and terminology. He must also be familiar with requirements of the building code and the standard code for arc and gas welding. After the oral examination, he must prove that he can weld in the various positions required. These sample welds are machined and tested for quality. For a Structural Steel-Shop license he must make approved welds in the horizontal and vertical positions as well as flat. The field license requires that he must weld overhead as well. A Lightgage welder must pass similar tests. His picture is attached to the license so there should be no doubt that the one using the license is the one that qualified. However, the mere possession of the license does not mean that every weld is satisfactory. The welding inspector must approve all welds and may require the welder to take new tests before doing structural welding. Here, let me say that a tack weld is not considered a weld unless it be at least one inch long and certification is not required for this welder. However, tack welds later incorporated into the work must pass the requirements. The inspector must be familiar with welding symbols in order to tell the type of weld the engineer is calling for. About 80% of all welds are fillet welds, 15% are butt welds, and only 5% are special type welds. I will not go into the subject of welding symbols in detail, however, I might say the symbol itself is not enough to describe a weld. The arrow must point to a corner or pieces to be welded and sometimes additional information is needed. Anything that is not clear should be brought to the engineer's attention for his clarification. The tail section of the welding symbol may be used to specify any unusual condition. Here, for

21313

Lack of fusion and cracks are cause to reject the weld and the welder. Any welds with these defects must be removed and rewelded. Poor fusion is caused by too low current setting, or improper technique or failure to properly prepare the joint or perhaps too large an electrode. There are different kinds of cracks in welds such as crater cracks, underbead cracks, and longitudinal cracks. The cause here is sometimes very difficult to determine. Perhaps the base metal is not weldable or the joints have not been properly prepared or wrong procedure or too rigid a joint will result in cracked welds.

A weld crater is a depression located at the end of each pass. Any arc welding process or procedure produces weld craters. The ability to fill this crater varies considerably with the welding current and weld size; but there is usually no problem if at the completion of a pass, the electrode travel is delayed sufficiently to fill the crater. All craters shall be filled to the full cross section of the weld. Draw the electrode away from the work slowly and on the next bead strike the arc a little ahead of the crater, hesitate momentarily, then move back over the crater and completely remelt and fill it. It is important to fill this crater because many cracks start in this relatively weak area. This is one reason that the length of a fillet weld, as called out on the drawings, is increased by twice the weld size to be sure that the sections where the welder started and stopped are not in the required length. Any questionable welds should be tested or rewelded.

To avoid some of these problems, the welding inspector should check out the procedure to be used, see that the polarity is correct and that the fit-up is tight. Also, if he can have the work positioned for flat welding it makes a great difference in appearance and quality.

A nondestructive method of testing requiring no electrical equipment involves the use of a dye penetrant. Imperfections such as cracks, laps, and porosity are indicated by lines, dots or blotches of a color easily detected visually. First the surface is cleaned. Then it is covered with a dye which is left on for five or six minutes. After removing with cleaner, a developer is applied. The color will remain in any crevices until it is drawn to the surface by the action of the developer. A colored line indicates a crack. A series of dots or blotches indicates a tight crack or unwelded area.

Other methods of nondestructive testing include magna flux, a method in which a piece of welded material is held in a magnetic field and the groupings and arrangement of iron filings indicate faults in the piece. This is an unwieldy process and is not used very much in larger welded pieces. The x-ray picture is another way to detect faults in welding. Here, the interpretation of the picture by experts takes time and is somewhat unwieldy. Ultrasonic sound waves and magnetic currents are others. However, because any of these methods may be called for by the inspector, the fabricator will usually decide to reweld the piece when requested by the inspector rather than argue the point.

21306

SHOP PROCEDURES

Now as to the shop procedure itself, when the order for steel is received by the fabricator, his first step is to prepare the detailed drawings. These are in two sections, the erection drawings which locate each piece and show its relation to the whole job, and the fabrication or shop drawings showing precisely how each piece is made. These drawings are sent to the structural engineer for his approval before any work is done. The erection drawings guide the field crew as to where each piece is located so that the actual erection can be done efficiently. Each piece of steel shown on the shop drawings is marked with an identifying letter and number to coincide with those on the erection drawings. Any changes in the fabrication must be approved and noted on these drawings. When the job is complete,the as-built drawings required will be corrected from these shop drawings and show what was actually done.

The shop drawings are the actual orders from the front office to the shop to make the beams, columns or girders, or whatever it may be. These drawings show precisely where each weld, hole, bolt or rivet is to be and what shape of steel member is to be used. Work lines are also shown on the shop drawings. These lines are the center lines of action of a member of a truss or other built-up section and must be correctly lined up to avoid eccentricity in the truss components. A list of the materials required is also on each drawing.

The inspector looks the drawings over for the engineer's approval which indicated the engineer has checked the drawings and found them in accord with the design drawings. The inspector has no authority to make a change. His responsibility is to secure compliance with the approved drawings and any change must be made by a change order. The shop drawings must have the approval of the engineer. However, the design drawings are still the contract drawings and any changes therefrom must be approved by the engineer and the Office of Architecture and Construction in the case of school work. Sometimes a minor clarification may be shown on the approved shop drawings without a change order. The inspector should compare the shop drawings with the design drawings and call the attention of the structural engineer to any changes even though they have been stamped approved unless the changes have been definitely marked as a change on the drawings.

Before use, the steel may be tested by a laboratory (if such tests are required) which issues a report stating the steel meets the specifications. The welding inspector looks for the laboratories' stamp and heat numbers to be sure the steel used is the same one tested. He also checks for the correct steel shape called for. In the shop a layout man assembles the required items, after any cutting or shearing; and if any multiple pieces are to be made, he makes a template out of stiff cardboard to show the outline and connections for a gusset plate, for example, in order to assure accuracy in every piece. He marks the location of any bolt holes.

The fitter tacks the assembled items together with a small weld, or bolts the parts together temporarily, and the item is then delivered to the welder. When the material is being laid out and fitted is the

21307

time for checking work lines, the relative location of members, built-in camber and location of holes and correct fit up for welding. Drilled holes are preferred to punched holes because the area around the punched hole is over stressed during the punching operation and therefore the immediate metal around the hole cannot be counted on to perform in the usual manner. However, punched holes are permitted if the metal being punched is not thicker than the diameter of the bolt plus 1/8 inch. Most fabricators now use a drill with a magnetic chuck to drill any required holes instead of the punch which is a relatively large fixed machine. Only on light material easily handled such as angles and small plates are punching machines still used. The magnetic chuck holds the drill in place and aligned straight on the work. As part of the check-up before welding, the inspector must see that the joint preparation is correct. The contact surfaces of all welded connections shall be free from any paint, oil or cutting slag and have straight edges. Clean surfaces and close fitting pieces eliminate many weld defects. The faying surfaces where the pieces connect for a fillet weld can have no more than 1/16 inch gap tolerance. The steel manual lists the details for welding structural connections. All butt welds must be full penetration welds. Butt welds with over 5/16 inch thick pieces must have at least one side beveled to allow room for the electrode to reach the root area. The details for various conditions depending on the thickness of the material are shown in the A.I.S.C. Manual and must be followed both as to gap required and beveling, back up strips and back gouging. It is necessary to have this bevel to allow not only the electrode to reach into the root area but to leave room for the protective gases to cover the weld as well. A new method of preparing groove welds is now in use in most shops. A carbon electrode with a thin copper coating is used together with a jet of compressed air. The electrode is used with an ordinary DC welding machine. The holder is so built that a jet of compressed air is directed at the arc so that the steel as it melts is blown away. The electrode can be used in any direction and the air jet is always aligned with the point of the arc regardless of position. Slag and molten steel are being constantly blown clear of the work leaving a clean surface. This system is much faster than grinding or chipping so that this new procedure is now used in making full penetration, 100% welds. The welder makes his pass on the reverse side merely holding a small gap between pieces to assure penetration. Then he changes his holder to one with the compressed air attachment and cuts through the joint from the front side until the root of the firts weld has been exposed and cleaned off. This removes all slag and opens the joint so that the filler passes can be easily done. This arcair torch makes a good tool for investigating suspected areas also. A cut can be made quickly in any weld and the interior of the weld can be visually inspected.

The effects of distortion must be considered when preparing to weld. Weld metal, in its molten state, is at its largest volume and when cooled it contracts across the weld, and if the connecting plates are not very firmly held in position, they will move in toward the weld as it cools. The amount of shrinkage depends upon metal type, thickness,

joint type, weld position, electrode type and size and welding method. Using the least amount of heat consistent with weld quality will help prevent distortion. This distortion is of concern because it will throw welded members out of line or cause warping in connecting plates. Even if the distortion is not apparent, a built-in stress may cut down on the safety factor. If a connecting plate has welding on the reverse side and is to be used with high strength bolts in a friction joint, for example, the distortion here will prevent the surface to surface flat contact required.

It is important when welding to allow as much movement as possible so that built-in stresses and distortion are held to a minimum. Where a wide flange shape is used as a column and welded to a base plate, the web is welded first to the base plate and then the flanges are welded to allow as much movement as possible to ease the strain. Warping in some instances may be compensated for by positioning the weld to anticipate the distortion. A strong frame holding the parts in position may prevent distortion and in some cases the distortion may be removed by heating and slowly cooling the affected area.

Any shop bolting or Nelson stud welding is done next. Bolts should be checked for grip, that is, the unthreaded portion if a full grip is called for. This grip should be equal to the thickness of the parts being joined and a washer then is required to assure a tight connection with no threads in the hole. If a full grip is called for, the design stress may be increased about 50%. Holes must be free from burrs so that the connection will be made tight. Then the material is straightened if any of these operations have tended to deform it and send to the painter. Check the piece for camber (the deviation from a straight line in the vertical plans) and for sweep (the deviation from a straight line horizontally). Heating the member to straighten it is permitted because the heating and cooling, even if water is used to hasten the cooling, has only a minor affect on the steel. After thorough cleaning, wire brushing and perhaps sand blasting the primer is applied unless the steel is to be encased in concrete. The pieces are marked according to the shop drawings and sent to the job. The actual erection process starts before the shop fabrication is barely begun, however. Anchor bolts must be placed and the wise steel shop will wait and take field measurements for the beams or girders after concrete is poured before fabricating the items. The job inspector should have a set of shop drawings as well as the erection drawings on hand. He also should be sure that the fabrication has been inspected either by finding an inspection stamp on the delivered pieces or other means. The erection of the steel framework is usually done by the fabricator's own crew. Sometimes, however, a special crew is used. The inspector can help by seeing that coordination between general contractor and the steel fabricator is maintained to be sure that embedded items are ordered to be ready when needed, for example, and that measurements shown on the design drawings are adhered to and that changes affecting the steel are passed along to the fabricator quickly. With the erection drawings showing the location of each piece, he can check the steel work. Anchor bolts must be accurately placed. A template should be used in multiple cases. Base plates setting on those anchor bolts must be leveled,

preferably by means of leveling nuts under the base plate at each bolt. Separate leveling plates should not be used as a rule because of the difficulty in getting a good contact with the column base plate. There must be at least 1" room for drypack under the base plate. According to Title 21, any bolt holes must not be more than 1/16 of an inch greater in diameter than the bolt. Most engineers, however, will allow some extra room in the case of anchor bolts. The frame shall be carried up true and plumb and temporary bracing shall be used to take care of all loads that may be encountered including wind loads while under construction. Particular care shall be taken to brace any girders, trusses or beams before leaving any steel frame. No final bolting or welding is to be done until the frame is properly aligned. Bolted connections shall be aligned by use of temporary bolts until all lower connections affected are in alignment. Forcing by means of driving drift pins in the holes to enlarge the holes is not permitted. As the erection progresses the work shall be securely bolted up or welded to take care of all dead load, lateral forces and erection stresses.

FIELD INSPECTION

The steel inspection in the field is not necessarily continuous unless multiple pass welding is being done or during the installation of rivets or high strength bolts. The inspector should be present when the anchor bolts are set and when the structure is plumbed and braced before the permanent connections are made. The location of anchor bolts in concrete is very important and even if field measurements are taken many times, remedial action is needed when the members are to be erected. Because of the hole allowance from Title 21 of only 1/16 inch greater than the bolt, a field problem is often encountered. Shop practice allows a larger hole, 3/16 to 5/16 larger, for anchor bolts because of the difficulty in securing the bolts exactly in place while pouring and vibrating concrete. Wall bearing beams and ledger angles may also have slotted holes to allow for minor differences. However, unless your drawings show a slotted or larger bolt hole, check with your engineer first. The anchor bolts have no deformations such as are found on reinforcing bars and develop their strength through bond with concrete and their hooks. They must not be hit with a sledge hammer to bring them in line with the hole. This could break the bond with the concrete. This is one item that should be checked out on the issuing of the drawings and settled before the item is made by alerting the engineer to the problem. It is rather late to discover this condition where you can't get the girder in the concrete chase or the bolts don't fit and the truss is hanging in the air and the crew is waiting. Anchor bolts must be cleaned of all oil so that they will bond to the concrete. If the bolt is short by one to three threads, the nut can be welded on the inside to the bolt; but if the bolt is still too short, an extension might have to be welded on. Here is where low-hydrogen electrodes must be used because of the possibility of a higher carbon steel. All bends in the anchor bolts must be checked and for that matter any bent plate should be checked for the presence of fracturing. The steel must be examined when it is delivered to be sure it has not been damaged during transit and that the paint is in good condition. Check the work against the approved drawings to see that the arrangement, size and number of bolts is correct and that the size and length of each weld corresponds with that shown on the approved drawings. All bolt holes must be fair

21310

and drifting of holes to alignment is not permitted. The nuts should be tested for tightness and complete thread. When field welding is to be done, the welder must be certified for all position welding, have a welding machine capable of furnishing sufficient current and have the right electrode for the job. For field welding the electrode should never be larger than 3/16 and for corrective items or difficult positions 1/8 inch diameter. The welder must have a wire brush and slag hammer. He will probably carry a torch and oxygen and acetylene tanks on his truck. Another item not carried by the field welder, but at times quite essential, is a fire extinguisher. When welding close to wood or other combustible material, this must be watched. The welder can't see the fire through his hood and it may be well along before discovered. Also, heating any structural member, especially reinforcing bars to facilitate bending, is not allowed. Gas cutting on members not designed, therefore, is not permitted except with the approval of the engineer and then only if the member is not under stress. It is often found that reinforcing bars have to be welded. This may be either to a mild steel plate or welded together as a butt joint or a lap weld. The procedure for welding reinforcing bars is given in the State Circular #6. The amount of lap is called out for various size bars and the profile of weld is shown. These lap dimensions must be followed. Also the low-hydrogen electrode must be used. For structural grade bars the electrodes shall be E60 series low-hydrogen electrodes. For intermediate grade use E70 electrodes and for hard grade use E60 electrodes. The E60 will have no end color, the E70 has a blue color and the E80 is white. An orange color spot on the side indicates the low-hydrogen rod. Check the unopened box for the exact classification and see that the rods are kept dry. Preparation of the joining surfaces must be done to assure penetration. The difficult part in welding reinforcing bars is to use only as much heat as necessary to get penetration and avoid the build up of excessive heat or weld. Pre-heating of large bars will prevent a too rapid cooling effect on the weld. Excess heat will cause the bar immediately adjacent to the weld to be brittle and it will invariably snap off right next to the weld. If there are a number of welds to be made, one method is to weld them a pass at a time. While one pass is cooling on one joint, a pass is welded on the next one and time allowed for the heat of welding to dissipate. At any rate, undercut is very serious and so is any overwelding on reinforcing bars. When welding to a flat surface, the deformations of the re-bar should be ground off for a better connection.

Miscellaneous steel including railings, ornamental fences, tank supports, decking and other items not found in the structural section of the specs are important too. Not only do some of these have structural value, usually they must present a pleasing picture to the eye and a poor weld or poor erection can hurt an otherwise good job.

The steel deck is frequently used as a horizontal shear panel, and the welding and installation is structural. Perimeter welding must be done as detailed and the welds between individual pieces must be sound in order to carry the continuity of forces. The welder must have a

Lightgage Welding certificate and use either a low-hydrogen electrode or an E6013. Puddle or plug welds to the supporting members are usually called for and must penetrate into the sub member and be slightly convex. Sometimes welding washers are used when the decking is comparatively thin. The hole in the washer is filled with weld metal, thus assuring a good connection.

On decking as well as bleachers and light standards and pipe columns we find galvanized material. This is a coating of zinc and aluminum put on in a dipping process. The galvanizing should be done in the largest practical units after fabrication. The zinc bath is about 600 to 900 degrees, and this heat sometimes poses a problem in that it allows built-in stresses of the welding to be relieved. This is shown by buckling of plates or warping of stringers or other deformations. The only remedy for this is not to put into the piece the stresses that could cause this deforming. This is done by either making the individual pieces small enough so that large stresses are not there or by having the members strong enough to withstand the stresses. This is another case where too much weld is bad. Overwelding can be as troublesome as underwelding. The galvanizing must be free from icicles or barbs and cover each piece completely. In the case of bleachers where one style is to use flattened pipe at the bolted connection particular care must be taken to see that the galvanizing enters into the seals of the flattened end. Also it is important in preparing pieces for galvanizing, to have no enclosed portion so that the hot air can't escape. Holes must be drilled into each piece to allow the expanded gas to get out when it is dipped. Welding on galvanized pieces does not produce structural quality joints. The galvanizing should be melted off in important field connections before welding. When the galvanized area is welded, the protective coating is lost, and the use of a galvanizing stick is recommended. The weld and surrounding area is heated to about 600 degrees by the gas torch and the stick is rubbed on and the melted galvalloy is brushed on with a wire brush. Aluminum or galvanized spray is sometimes used but will not last as long. New paints are being developed that have zinc in suspension, such as Galvicon or Dry Galv. and can be used in the field. But galvanizing at best is not for looks but merely to protect the steel from rusting, which it does very well.

I have tried to present something about steel fabrication in this area. Of course there is much more to it than what I have said, but it is a very interesting field and I am sure that the more you know about it the more you appreciate it. There is always something new and different, faster and more efficient, challenging ideas and methods where progress is shown illustrating the ingenuity of modern design and materials with the safety built in by the engineer and guaranteed by the inspection.

UNIT III - STRUCTURAL METALS

SOURCES OF MATERIAL TO BE INCLUDED IN LECTURE NOTES

1. Chapter 2 of Structural Steel Design by Lynn S. Beedle & et al., The Ronald Press Company, New York, New York.
2. Pages, 155, 156, 157 of Section 5 of the AISC Manual of Steel Construction, American Institute of Steel Construction, 101 Park Avenue, New York, New York 10017.
3. Pages 4 to 11 & 125 - 125 of the Standards for Aluminum Mill Products, the Aluminum Association, 420 Lexington Avenue, New York, New York 10017.
4. Structural Steel Inspection by A. A. Anderson, Steel Inspector, Los Angeles Board of Education, 1425 South San Pedro, Los Angeles, California 90015.
5. Welding Procedures at Kaiser Steel Fabricating Division, C. A. Zwissler, Manager of Construction Marketing, Kaiser Steel Corporation, 200 Lakeside Drive, Oakland, California 94604.

UNIT IV - MASONRY

Course for Inspectors, Quality Control of Masonry

A. Introductory

References

1. Objective: The objective of this course is to provide an outline and subject material for the teaching of inspectors responsible for the quality control of masonry. It will provide an outline and will list some of the reference material that can be used to amplify and augment that outline, leaving it up to the individual instructor to provide the detail amplification of the material as best suits his skill and talent.

2. Function of the Inspector: The function of the inspector is to help bring into being the dream behind the creation of the plans for the project, to assure that the intent of the plan and specs is realized.

   "Reinforced Grouted & Brick Masonry Field Inspectors Handbook"

3. Codes: The inspection may be performed under various jurisdications, for example, Uniform Building Code of various year issues or Title 21 of the State Office of Architecture & Construction, or Los Angeles City or San Francisco, and, in addition, will have specific requirements from the design offices for some particular reason. The inspector should acquaint himself with these differences so that, for example, he does not enforce high quality school requirements upon lower quality warehouse construction, or does not permit warehouse construction in high quality school work. Each is suitable in its own place.

   "Reinforced Concrete Masonry Inspectors Manual"

B. Materials

1. Terminology:

   a. Become familiar with the correct connotation of the language or masonry "dialect."
   b. Check specifications to note use of unusual items.
   c. Glossaries.

   Journal of the Structural Division, ASCE, Reinforced Masonry Inspectors Manual; Reinforced Grouted Brick Masonry Field Inspectors Handbook

2. Specifications:

   a. General: Job specs versus reference specifications, care in use of reference specs. ASTM Standards
   b. Reference Specifications:

      C 150 - Cement
      C 5 - Quick Lime
      C 207 - Hydrated Lime
      C 144 - Mortar Aggregate
      C 404 - Grout Aggregate
      C 476 - Mortar & Grout for Reinforced Masonry
      C 216 - Facing Brick
      C 62 - Building Brick
      C 67 - Sampling and Testing Brick
      C 126 - Ceramic Glazed Structural Clay
      C 34 - Clay Load Bearing Tile
      C 55 - Concrete Brick
      C 90 - Load Bearing Concrete Block
      C 140 - Sampling, Testing of Concrete Masonry
      A 15 - Rebar
      A 82 - Wire

3. Sampling:

   a. General: The field inspector is frequently responsible for the sampling of materials which are to be tested by the laboratory and care must be exercised because improper sampling can result in test results indicating failures which causes considerable concern and lack of confidence in the job and needless upsetting of the proper conduct of the project.
   b. Sand: Representative sampling is difficult, due to flow segregation. What to do?
   c. Reinforcing: Generally checking of tags and mill reports.
   d. Aggregate.
   e. Block: One method is to follow the CMA Q Quality Control Program. Q-Block Program
   f. Brick: Representative samples should be taken - not all light or dark
   g. Mortar: by spreading on masonry.
   h. Grout: Cast in absorbative molds of the masonry being used on the job.
   i. Coring: Done by professional organizations. However, careful note should be made of the taking and handling, as well as determination of proper location.

4. Testing:

   a. General: In general, there is not a great deal of testing to be done by the field inspector; however, he must check the specifications and determine what are the requirements in the specifications for testing and confirm or check to see that such testing has been done and that the materials are satisfactory and in compliance with the specifications for the project.

V-A-3 Subgrade or Basement Soils

Subgrade or basement soils constitute the basic foundation of the pavement upon which the structural section will be placed. It must be brought to grade by cut and fill operations and must be compacted to the specified requirements to prevent future settlements which can be destructive to the pavement.

In the previous course, Structural Series #1, earthwork was covered to include cuts, fills and compaction. We recommend that this portion of SS #1 be reviewed, to include references at this time, for refreshment on the techniques in earthwork construction.

Inasmuch as drainage is such an important subject, we wish to emphasize again that wet spots, springs, etc., are likely to be discovered in construction and may require a change in the drainage plans. The engineer who prepared the plans should be consulted where discrepancies may exist and changes made before proceeding. It becomes expensive to correct drainage problems when they show up after the pavement has been placed.

V-A-4 Subbase Construction

Subbases, when used, are generally composed of granular materials. Specifications for these materials will contain a minimum strength requirement (R-Value or CBR), a gradation requirement with broad limits and a plasticity limit (sand equivalent or plasticity index). Subbase materials are of lower quality than bases and are used for economic reasons. They may be treated, however, seldom are treated in Western practice in flexible pavement construction. Rigid pavements on California highways are built over a cement-treated base on a granular subbase, however, a layer of imported material directly under the slab is most generally referred to as the subbase.

Prior to placing subbase material, the subgrade is to be properly compacted and brought to the grading plane (the top of the subgrade or basement soil elevation). Specifications will generally allow some tolerance in grade, such as that contained in the California Standard Specifications of $\pm$ 0.10'. The specifications also should contain a smoothness requirement such as $\pm$ 0.05' variation when tested with a 10' straightedge. The chances of building a smooth pavement over a rough subgrade are poor; therefore, working within the tolerances specified is required.

In placing the subbase, segregation must be avoided. Placement in windrows and spreading with a blade is generally the method used in highway construction. It can also be placed using spreader boxes which strike off the material at a certain depth. End dumping should be avoided if possible to prevent segregation. Thickness limits are generally specified for the layers to insure the lifts are capable of being properly compacted. Remember, again, that strength is governed by the degree of compaction.

Compaction of the subbase may be accomplished with pneumatic rollers, steel wheeled rollers, vibratory rollers and segmented steel wheeled rollers. To obtain maximum density, the subbase material should be kept at or near optimum moisture by adding water as necessary. The specification will spell out the density requirement or the rolling procedures to follow. Testing for density was covered in Structural Series No. 1, however, briefly it requires that the density of the field sample bear a certain relation to a specimen compacted by certain methods in the laboratory.

$$\text{Relative density (\%)} = \frac{\text{Field density (lbs/ft}^3)}{\text{Laboratory density (lbs/ft}^3)} \times 100$$

Test methods (AASHO) are shown in the Soils Manual (MS-10) and the Asphalt Paving Manual (MS-8) distributed by The Asphalt Institute and used as texts in these courses.

Specifications will generally contain a finished grade tolerance and a smoothness requirement similar to those for subgrade but with

less variation allowed. For instance, the California Division of Highways Standard Specifications state that the grade shall be within $\pm$ 0.08' of that set by the engineer. Smoothness requirements are set for Navy Airfields at 3/8" variation when tested with a 10' straightedge. Highway requirements are sometimes set greater than this amount because surface smoothness is not as critical because of slower speed traffic.

Aggregate subbase is generally paid for by the ton or cubic yard in highway and airfield work, however, in small jobs may be included in the square foot cost of the completed pavement.

The thickness of the subbase should be checked after compaction occasionally to see that you are in fact obtaining the thicknesses required by the plans. This may be accomplished when making the compaction test if the sand volume method is used.

(4) On aircraft for which there is no approved flight manual required, the operating limitations prescribed during original certification and as required by FAR 91.31 must be carried in the aircraft. Where appropriate, these can be range markings on the instruments. Another method may be in the form of typed data on cards similar to 3" x 5" file cards. For convenience these can be covered with clear plastic and mounted in a conspicuous place in the cabin or cockpit. See Figure 5.

f. Completion of the FAA Form 8320-3. Within 48 hours after completion of the annual inspection, the Aircraft Use and Inspection Report, FAA Form 8320-3, should be completed and mailed to the local General Aviation District Office. Advisory Circular 43.11-1B, Aircraft Use and Inspection Report, or subsequent revision, describes how to complete the form. See sample form in Figure 6. For use of the form on progressive inspections, see FAR 43, Appendix C. The forms may be mailed without folding unless the aircraft is reported as "unairworthy." In this case, the discrepancy list may be enclosed by folding and stapling the form.

g. Aircraft Markings. It is the owner/operator's responsibility to have the nationality and registration marks properly displayed on the aircraft. (FAR 91.31(c).) AIs can, and should, offer advisory service to owners and operators in regard to any deficiencies in marking; however, they are not cause to report an aircraft "unairworthy." FAR 45 sets forth the required identification markings of aircraft.

h. Inspection Reminder. Encourage owners to use the inspection reminder, FAA Form 8320-2. When you perform an annual inspection, complete the inspection due date and install the sticker in a conspicuous place in the cockpit or where it will be seen during a preflight inspection. (Inspection date September 15, 1966; due date September 30, 1967.) See the example in Figure 8.

i. Unairworthy Aircraft. If the aircraft is not approved for return to service, use the procedures specified in FAR 43.11(a)(5). This will permit an owner to assume responsibility for having the discrepancies corrected prior to operating the aircraft.

(1) The discrepancies can be cleared by an A&P mechanic unless they consist of major repairs or alterations. If preventive maintenance, they could be cleared by an owner or pilot.

(2) The owner may want the aircraft flown to another location to have repairs completed, in which case he should be advised that a special flight authorization (ferry permit) is necessary. Have him contact the FAA GADO for the authorization.

2. Solid Reinforced Brick Masonry

   a. Site & preparation
   b. Types of details
   c. Sample panels
   d. Absorption
      (1) ASTM requirements
      (2) The effect of these requirements
      (3) The control of these requirements
   e. Bed and head joints
      (1) Furrowing
      (2) Filling of head joints
      (3) Tapping of brick
      (4) Shoving of joints
      (5) Tooling of joints
   f. Grouting procedures for low lift
   g. Grouting procedures for high lift

3. Veneers

   General: There have been many arbitrary requirements in veneer and many different types of specifications and code limits on veneer. Therefore, it would be well for the inspector to check that the detail specified is completely specified and question items possibly not covered, such as unusual conditions. Although there are many arbitrary requirements in veneers, the new Uniform Code requirements classify two types of veneer, namely adhered veneer and anchored veneer, and provide the requirements necessary to design these items. These codes also permit the use of arbitrary methods which have proven satisfactory over the years, some of which may not be in compliance with those basic requirements. In the interest of clarification, these different types have been outlined.

4. Adhered Veneer

   a. Types, such as thin ceramic units, thin brick, special thin stone, etc. (Reference)
   b. Specification. The type that has proven satisfactory was first developed by and included in the Los Angeles City Code.
   c. The basic procedure for this is to dampen the two elements to be bonded, then brush them with neat cement slurry and apply mortar to each which is squeezed together, developing the bond.

21319

d. Weather: If the weather is unusual, e.g. unusually hot, the inspector should check with the engineer as to need for expansion joints. Also if the conduct of the work is such that the veneers will be applied on concrete surfaces still undergoing initial shrinkage, the inspector should check with the engineer for need of such joints. In hot weather inspector should be very careful to see that the backing and the veneer units are thoroughly damp at time of setting.

5. Anchored Veneer of Stone or Masonry Units

6. Anchored Veneer of Slab Type Units

   a. General
   b. Examples, such as marble, stone, travertine, precast concrete, ceramic veneer.
   c. Typical details and anchors.

7. Masonry Units and Stone Veneer on Paperback Mesh

   a. General: This is sometimes called an anchored veneer and sometimes an adhered veneer. It consists of laying up a wythe of masonry and then pouring grout behind to bond the masonry to the mesh attached to the supporting structure.
   b. Mortar might be used in some cases for adhering the veneer, but only if the veneer is shoved into the mortar; otherwise the mortar bond, from slushing, will not be adequate.
   c. Specifications require development of fifty pound per square inch shear on this type of unit, and if there are questionable areas, they should be checked and marked by cord ruling.

8. Specific Miscellaneous Types

   a. General: Many items are developed specifically by test and have specific approval.
   b. Bowers tie
   c. Paper backed mesh (above)
   d. Special anchors

UNIT V - PAVING

V-A-1 Introduction

This portion of the course consists of three sessions on paving, as follows:

V-A Earthwork, Subgrade Preparation, Aggregate Bases and Subbases

V-B Asphalt Paving

V-C Portland Cement Concrete Paving

Pavements are designed to carry loads like any other structure. Generally, the heavier the load the thicker the pavement must be to adequately carry the load without failure. As other materials vary in strength so do the materials used in pavements, however, pavements, that is, soil, rock, asphalt concrete or portland cement concrete, are fabricated in the field and the handling of these materials can affect the strength and durability of the final product.

The designer will specify the quality of the materials, how they are to be handled, the thicknesses of lifts, the degree of compaction required, as well as where to place them and at what grade. The inspector's job is to see that the design is built according to the plans and specifications.

The cross sectional sketches shown here serve to illustrate the various elements of the pavement. In addition, they show three common cross sections built to carry loads:

HEAVY DUTY ASPHALT PAVEMENT

LIGHT DUTY ASPHALT PAVEMENT

RIGID PAVEMENT

A (Light)

B (Medium)

C (Heavy)

There are many other variations of the sections; the use of stronger materials, such as asphalt, cement or lime-treated aggregates or soils, will make the structural section thinner. The structural section composition will be governed by the section which costs the least to build.

UNIT V - PAVING

Asphalt Specifications

1. Asphalt Cements or Paving Grades

The Uniform Pacific Coast Specifications for paving asphalt, as shown in Table 1, were adopted by Pacific Coast user agencies in 1957. They are in general use on the Pacific Coast, although other specifications are occasionally used here by national specification writing agencies. Paving asphalt meeting Pacific Coast specifications will comply with Asphalt Institute and other national specifications.

TABLE I
UNIFORM PACIFIC COAST SPECIFICATIONS FOR PAVING ASPHALTS*

Specification Designation	AASHO Test Method	Grade				
		40-50	60-70	85-100	120-150	200-300
Flash Point-- P.M.C.T. °F., Min.	T73	460	450	440	425	400
Penetration of Original Sample at 77°F.	T49	40-50	60-70	85-100	120-150	200-300
Loss on Heating, 5 hr. at 325°F., % Max. (Calif. Test Method No. 337, Thin Film Procedure)	--	0.75	0.80	0.85	1.00	1.50
Pen. after loss at 325° F., % of Orig. Pen., Min.	T49	52	50	47	44	40
Ductility at 77°Fs, cm. after loss at 325° F. Min.	T51	50	50	75	75	75
Penetration Ratio $\frac{\text{Pen. 39.2°F.-200 gm.-1 Min.}}{\text{Pen. 77°F.-100 gm.-5 Secs.}} \times 100$	T49	25 Min.	25 Min.	25 Min.	25 Min.	25 Min.
Furol Viscosity at 275° F.	T72	120-430	100-325	85-260	70-210	50-150
Solubility in CCl_4, % Min.	T45	99	99	99	99	99
Heptane Xylene Equiv., % Max.	T102 (Modified as noted below**)	35	35	35	35	35

* These specifications were adopted by Pacific Coast user agencies in 1957 and are in general use on the Pacific Coast, although other specifications are occasionally used here by national specification writing agencies. Paving asphalt meeting Uniform Pacific Coast Specifications will comply with Asphalt Institute and other national specifications.

**Normal spot test and glass plate test repeated at end of 24-hour period will not be required.

2. Liquid Asphalt Specifications

The Specifications for Liquid Asphalts are given in Tables III, IV, and V. Table VI shows the alternate Viscosity Specifications in Saybolt Furol seconds. The viscosity specifications are illustrated graphically in Figure 2.

In these specifications, the nomenclature for type is based on the curing rate, i.e., RC (Rapid Curing), MC (Medium Curing), and SC (Slow Curing). The numerical designations within the types correspond to the minimum viscosity in centistokes at 140 degress F. For example, RC-70 is the most fluid

Rapid-Curing Liquid Asphalt and has a viscosity range at 140 degrees F. of 70 to 140 centistokes. RC-3000 is the most viscous Rapid-Curing Liquid Asphalt and has a viscosity range at 140 degrees F. of 3000 to 6000 centistokes. Thus, the designation number relates directly to the minimum viscosity for the grade. Note that the upper viscosity limit is twice that of the lower limit. The table of recommended uses of asphalts (Table No. II) includes liquid asphalts and their primary uses in construction.

TABLE III

[1] As an alternate for kinematic viscosity limits included in specifications on Tables III, IV, & V, Furol Viscosity limits may be used. These Furol Viscosity limits may be specified, as shown above, either at a constant temperature (140°F.) or at three temperatures. This alternate is provided in recognition of the transition period required in changing from the Saybolt Furol test to the more fundamental kinematic viscosity test.

Fig.2-GRADES OF LIQUID ASPHALT, VISCOSITY AT 140° F

UNIT V - PAVING

V-A-5 Base Construction

Bases are considered by some to be the main load carrying portion in a flexible pavement. When we consider a simple pavement consisting of a surface treatment over an aggregate base on subgrade, the base must withstand the shearing forces of surface loads and reduce the loads transmitted to the subgrade to the point where the subgrade will not be overstressed and fail. In multi-layer pavements the same type of load distribution is carried out from layer to layer. The base then becomes one distributor in a series which alters the load to the point where the subgrade will not fail. The mechanism is more complicated than this, however, it serves to illustrate in general the function of the layers. The load ultimately is carried by the subgrade and the pavement is a distributing agent.

The base is a layer under the surface with a primary load distribution function. It is not as efficient in this function as the surface (which must also resist abrasion by traffic) but more efficient than the subbase. Therefore, we can expect the quality of the base material to lie somewhere between the high quality surfacing and a lower quality subbase. This in-between quality position is, in fact, where we find base material quality.

Aggregate bases require more stability, more careful gradation control and less plasticity in their specifications than do subbases. To illustrate, the requirements for Class 2 aggregate bases and subbases specifications are shown as defined in the California Division of Highways Standard Specifications dated July 1964:

Class 2 Aggregate Base -- Aggregate for Class 2 aggregate base shall be free from vegetable matter and other deleterious substances.

The coarse aggregate (material retained on the No. 4 sieve) shall consist of material of which at least 25 percent by weight shall be crushed particles as determined by Test Method No. Calif. 205.

The percentage composition by weight of aggregate base shall conform to one of the following gradings when determined by Test Method No. Calif. 202.

Sieve Sizes	Percentage Passing	
	1½" Maximum	¾" Maximum
2"	100	---
1½"	90-100	---
1"	---	100
¾"	50- 85	90-100
No. 4	25- 45	35- 55
No. 30	10- 25	10- 30
No. 200	2- 9	2- 9

The aggregate base shall also conform to the following quality requirements:

Tests	Test Method No. Calif.	Requirements
Resistance (R-Value)[1]	301	78 Min.
Sand Equivalent	217	30 Min.
Durability Index	229	35 Min.

[1]The R-Value requirement will be waived provided the aggregate base conforms to the specified grading and durability and has a sand equivalent value of 35 or more.

Aggregate Subbase -- Aggregate for Class 1, Class 2, and Class 3 aggregate subbases shall be clean and free from vegetable matter and other deleterious substances.

The percentage composition by weight of Class 1, Class 2, or Class 3 aggregate subbases shall conform to the grading shown in the following table for the class specified when determined by Test Method No. Calif. 202.

Sieve Sizes	Percentage Passing		
	Class 1	Class 2	Class 3
3"----------	100	100	100
2½"----------	90-100	90-100	90-100
No. 4----------	35- 70	40- 90	50-100
No. 200----------	0- 20	0- 25	0-30

Class 1, Class 2, and Class 3 aggregate subbases shall also conform to the quality requirements shown in the following table for the class specified.

Tests	Test Method No. Calif.	Requirements		
		Class 1	Class 2	Class 3
Sand Equivalent	217	20 Min.	20 Min.	20 Min.
Resistance (R-Value)[1]	301	60 Min.	50 Min.	40 Min.

[1]The R-Value requirement will be waived provided the aggregate subbase conforms to the specified grading and has a sand equivalent value of 25 or more.

You will note the base minimum stability is higher as well as the Sand Equivalent. The base also has more stringent gradation requirements, crushing requirements and a durability requirement.

The sand equivalent is a measure of the amount of deleterious fines in an aggregate mixture. The higher the sand equivalent, the better the quality of the material. (See Soils Manual, MS-10, p. 241, for test method. The quality it measures is similar to that measured

by the Plasticity Index.

Aggregate bases should be placed using equipment that will prevent segregation of the fine and coarse aggregates. Dampening of the aggregates also helps prevent segregation.

Maximum compacted lift thicknesses are generally considered to be 6 inches compacted depth. If the base thickness is greater than 6 inches, it should be placed in two or more lifts.

The balance of the base placement requirements are similar to those for subbases with the exception that the smoothness requirements and grade tolerances are generally more stringent than for subbases.

Treated bases are sometimes used for greater efficiency in distributing loads. They are thinner than equivalent strength aggregate bases. It is considered beyond the scope of this course to discuss in detail construction of these bases, however, you may obtain information concerning this type of work from the nearest offices of The Asphalt Institute for asphalt-treated bases or the Portland Cement Association for cement-treated bases.

UNIT V - PAVING

V-B-1 Asphalt Paved Surfaces

There are several types of asphalt surfaces commonly used. They vary from a light spray application of a low viscosity asphalt to a thick layer of high quality asphalt concrete used in heavy duty highway, airfield and industrial yard construction. As we have noted before, the type of surface will depend upon the use the pavement is expected to receive.

Four common surfaces are described:

1. Penetration treatment - A spray application of a low viscosity liquid asphalt on the surface of an aggregate base. The asphalt penetrates the top 3/4 to 1" binding the particles together to resist abrasion and prevent the entrance of excess water.

2. Seal Coats - A spray application of asphalt followed by a cover of one size aggregate over a penetration treatment or an old surface. The function of the asphalt is to seal against the entrance of moisture. The function of the aggregate is to carry the traffic. The aggregate may vary from a sand (sand seal) to a crushed aggregate chip (chip seal). These applications may consist of one application of asphalt and aggregate (single seal) to two or more applications of asphalt and aggregate (multiple seals).

3. Road Mix Asphalt Surfacing - This surface is built by either mixing the native material in place or an imported graded aggregate with an asphalt of low viscosity on the roadbed. The depth of the treated material is generally 2

to 4 inches. It provides a low cost surfacing that toughens with time as the asphalt cures.

4. Asphalt Concrete Surfaces - This is a surface of the highest quality composed of well graded aggregate hot mixed with asphalt cement in an asphalt plant. It is generally placed with a paving machine and well compacted to provide a tough, smooth surface for traffic use. It can be placed over old pavements, aggregate bases, road mixed asphalt or cement treated bases or asphalt concrete bases.

UNIT V - PAVING

V-B-2 Asphalts Used in Paving, Specifications, Tables and Uses

Classification of Asphalts

Most asphalts today are obtained from the refining of selected petroleum crude oils. The heavier or more viscous portions of these crude oils are asphalts. The breakdown of such a crude is shown schematically in Figure 1. This is merely a schematic representation of the constituents of crude oil. The proportions will vary depending upon the particular crude.

There are three general types of asphalt used to construct and maintain pavements:

1. Paving Asphalts
2. Liquid Asphalts
3. Emulsified Asphalts

1-PETROLEUM ASPHALT FLOW CHART

UNIT V - PAVING

Grading of Asphalts

All asphalts are graded on the basis of consistency. The hardest paving asphalt (i.e. the most viscous) is the 40-50 penetration grade, and the softest (i.e. the least viscous) is the 200-300 penetration grade. The penetration test at 77°F. is used to determine these grades. Still softer asphalts are termed liquid asphalts (RC, MC, and SC). The kinematic viscosity test is used to grade these.

Liquid asphalts are graded by viscosity at 140 degress F. - RC-, MC-, and SC-3000 liquid asphalts have the highest viscosity, while RC-, MC-, and SC-70 have the lowest viscosity. Liquid asphalts are also graded by the type of solvent used to "thin" the paving asphalts, thereby enabling them to be handled at lower temperatures. Rapid curing (RC) liquid asphalts are produced by dissolving a paving asphalt in a naphtha-type solvent. Medium curing (MC) liquid asphalts are produced by dissolving paving asphalt in a kerosene-type solvent. Slow curing (SC) liquid asphalts are produced by either reducing the crude directly to grade by the distillation process, or by fluxing a paving asphalt with a light oil.

Emulsified asphalts are produced by dispersing paving asphalt into water by means of high-speed agitators and an emulsifying agent. There are two types of emulsified asphalts - cationic and anionic, depending on the type of emulsifying agent used in production of the product. These two types are further classified by the rate of setting of the emulsion; that is, the rate at which the dispersed asphalt particles will recombine and form a continuous film of asphalt cement.

There are four grades of rapid setting (RS) emulsified asphalts - RS-1, RS-2, RS-2K, and RS-3K. The K designation refers to the cationic type of emulsified asphalt.

The viscosity of the RS-1 and RS-2K are similar, as are the viscosities of RS-2 and RS-3K. The numerical designation indicates the minimum percent of asphalt as follows:

1 . . . . . 57%
2 . . . . . 60% or 62%
3 . . . . . 65%

The RS-1 and RS-2K have a low viscosity, while the RS-2 and RS-3K have a higher viscosity to reduce run off on grades and superelevations.

There are five grades of medium and slow setting (SM and SS) emulsified asphalts. These grades are used for mixing with aggregates or where dilution with water is desirable. The SS-1 and SS-1h are similar except that the base asphalt in SS-1h is harder than in SS-1. The cationic emulsified asphalts are designated SS-K, SS-Kh and SM-K.

3. Emulsified Asphalt Specifications

Specifications for the nine grades of emulsified asphalts in general use on the Pacific Coast are given in Tables VIIA and VIIB. Primary uses of these grades are also given in the table of recommended uses, Table II.

TABLE VII A

SPECIFICATIONS FOR ANIONIC EMULSIFIED ASPHALTS

Characteristics	AASHO Test Method	ASTM Test Method	GRADES			
			Rapid Setting		Slow Setting	
			RS-1	RS-2	SS-1	SS-1h

[1] Except that distilled water is used instead of sodium oleate solution.

[2] Except that carbon tetrachloride is used instead of carbon disulphide as solvent, Method No. 1 in AASHO Method T 44 or Procedure No. 1 in ASTM Method D 4.

Notes a) "K" in grade designations signifies cationic type

b) In Medium Setting Grade "SM" indicates sand mixing grade

Danville, Illinois
February 9, 1965

Mr. Robert D. Thomas
606 Elm Street
Urbana, Illinois

Dear Mr. Thomas:

This is to certify that on February 9, 1965, I completed an annual inspection on your aircraft Zeph-Air 63-1A, S/N 63-11046, N 40023, and found it to be in unairworthy condition for the following reasons:

1. Engine logbook entry indicates that the engine had been overhauled but had not been approved for return to service as required by section 43.5 of the Federal Aviation Regulations.

2. Fabric on both horizontal stabilizers tests below allowable minimum of 56 lbs.

3. Number three cylinder compression checks below manufacturer's recommendations.

Your aircraft will be considered to be in an airworthy condition when the above listed discrepancies have been corrected and approved for return to service by a person authorized in Part 43 of the FARs.

George B. Jones

George B. Jones

Temperature-Volume Corrections for Asphalt

Asphalt changes in volume with change in temperature. Change in unit volume, per degree change in temperature, is termed "Coefficient of Expansion," a factor which varies with the specific gravity of the asphalt. A temperature of 60 degrees F. is customarily used as the standard basis for volume determinations of asphalt and other petroleum products. Therefore, if the volume is actually measured at any temperature other than 60 degrees F., a correction factor must be applied to convert the measured volume to volume at 60 degrees F.

The American Society for Testing and Materials prepared and published extensive tables on temperature-volume corrections of petroleum products. These tables appear in a book entitled "ASTM-IP Petroleum Measurement Tables," published in January 1953 (ASTM Designation D 1250). Temperature-Volume correction tables contained herein have been extracted from this ASTM publication.

Temperature-Volume correction factors are given in the following tabulations for asphalt having a specific gravity at 60 degrees F. above 0.966 (designated by ASTM as Group 1 materials), and for emulsified asphalts.

Liquid asphalts of grades RC, MC, and SC 250, 800, and 3000, and all paving asphalts fall into the Group 0 classification. Use Table X for volume corrections.

Liquid asphalts of Grades RC, MC, and SC 70 fall into Group 1. Use Table XI for volume correction.

Use Table XII for temperature-volume correction factors for emulsified asphalts.

EXAMPLE OF USE. Assume an MC 250 grade of liquid asphalt. Assume also that a volume of this material is measured to be 9,000 gallons at a temperature of 180 degrees F. Determine the volume of this material at the standard temperature of 60 degrees F.

METHOD. MC 250 grades are in Group 0. Opposite a temperature of 180 degrees F. in the tabulation for Group 0 materials, the correction factor is determined to be 0.9587. Multiply 0.9587 x 9000 gallons which gives a volume at 60 degrees F. of 8628 gallons.

TABLE X

TEMPERATURE—VOLUME CORRECTIONS FOR ASPHALTIC MATERIALS

TABLE XI

TEMPERATURE—VOLUME CORRECTIONS FOR ASPHALTIC MATERIALS

GROUP 1—SPECIFIC GRAVITY AT 60°F OF 0.850 TO 0.966

LEGEND: t = observed temperature in degrees Fahrenheit
M = multiplier for correcting oil volumes to the basis of 60°F

t	M	t	M	t	M	t	M	t	M	t	M	t	M	t	M	t	M	t	M

Sampling of Asphalt

In order to properly test asphalt for compliance with specifications, it is necessary to take a representative sample. Samples taken in the field should be forwarded immediately to laboratory for testing.

Spraying and Mixing Temperatures

Table VIII provides a guide for use in determining application temperatures for asphalt.

The temperature of asphalt drops about 1 degree F. per hour in transit. (This varies with loading and atmospheric temperatures, and amount and type of insulation on the vehicle.)

Destination temperatures cannot be guaranteed.

Shipping of Asphalt

ADVANCE SCHEDULES. The shipping of asphalt is highly seasonal, and is sometimes accompanied by temporary shortages of transportation equipment. For this reason, service can be improved if the customer will furnish the supplier with a definite shipping schedule as far as possible in advance of the required date of shipments.

21347

TABLE VIII
SUGGESTED TEMPERATURES FOR USE OF ASPHALTS

Grade of Paving Asphalt	Distributor Spraying Temp., °F.		Pugmill Mixing Temperature of Aggregates, °F.	
	Min.	Max.	Min.	Max.
40 - 50 pen.	*	*	300	350
60 - 70 pen.	295	350	275	325
85 - 100 pen.	290	350	275	325
120 - 150 pen.	285	350	275	325
200 - 300 pen.	275	325	225	275

Grade of Liquid Asphalt	Distributor Spraying Temp., °F.		Pugmill Mixing Temperature of Aggregates for MC & SC Liquid Asphalts, °F.	
	Min.	Max.	Min.	Max.
RC, MC, SC Grade 70	120	180	95	140
RC, MC, SC Grade 250	165	220	135	175
RC, MC, SC Grade 800	200	255	165	205
RC, MC, SC Grade 3000	235	290	200	240

Grade of Asphalt Emulsions	Distributor Spraying Temp., °F		Pugmill Mixing Temperature of Aggregate, °F.	
	Min.	Max.	Min.	Max.
RS-1, RS-2K	75	130	(Not used	
RS-2, RS-3K	110	160	for mixing)	
SS-1, SS-K	75	130	50	130
SS-1h, SS-Kh	75	130	50	130
SM-K	100	160	60	140

* Seldom used for spraying

Stockpile mixes should be mixed at lower temperatures.

Pugmill mixing temperatures for open graded mixes should be between 225°F. and 250°F.

CAUTION: The purpose of the above table is to indicate temperature ranges necessary to provide proper asphalt viscosity for spraying and mixing applications for the grades of asphalts shown. It must be recognized, however, that temperature ranges indicated by this table generally are above the minimum flash point for the RC, MC and SC liquid asphaltic materials as specified by The Asphalt Institute and other agencies. In fact, some of these liquid asphalts will "flash" at temperatures below these indicated ranges. Accordingly, suitable safety precautions are mandatory at all times when handling these liquid asphalts. These safety precautions include, but are not limited to, the following:

(1) Do not permit open flames or sparks of any kind close to these materials except in heating kettles, mixers, distributors, or other equipment properly designed and approved for handling and applying them.

(2) Do not use an open flame to inspect or examine drums, tank cars, or other containers in which these materials have been stored.

(3) Properly vent and ground all vehicles transporting these materials.

(4) Permit only experienced personnel to supervise the handling of these materials.

(5) Comply with all applicable intra- and interstate commerce requirements.

TABLE IX
AVERAGE WEIGHTS AND VOLUMES OF ASPHALTS

Grade	Gallons per Ton @ 60° F.	Barrels per Ton @ 60° F.	Pounds per Gallon @ 60° F.	Pounds per Barrel @ 60° F
LIQUID ASPHALTS				
70	253	6.03	7.90	332
250	249	5.93	8.03	337
800	245	5.83	8.16	343
3000	241	5.74	8.30	349
PAVING ASPHALTS				
40 - 50 pen.	235	5.60	8.51	357
60 - 70 pen.	235	5.60	8.51	357
85 - 100 pen.	235	5.60	8.51	357
120 - 150 pen.	237	5.64	8.44	355
200 - 300 pen.	239	5.70	8.36	353
EMULSIFIED ASPHALTS				
All Grades	240	5.71	8.33	350

The average number of gallons per ton for the various types and grades of asphalt, as well as additional useful information, is shown in Table IX.

While actual weights may vary slightly, weights of asphalts used on the Pacific Coast may be considered uniform for all ordinary purposes.

21348

displacement by wind or traffic. SC-70, MC-70, or a diluted SS type is recommended.

2. Prime Coat - A spray application of a low viscosity asphalt on an untreated base preparatory to construction of the asphalt pavement or surfacing.

   For tightly bonded bases in hot climates, MC-70 or SC-70 is recommended. In cooler climates where curing may be slow, RC-70 is suggested.

   For open bases in hot climates, MC-250 is recommended. In cooler climates where curing may be slow, RC-250 is suggested.

3. Tack Coat - A very light spray application of asphalt on an existing paved surface to promote bond between this surface and the subsequent course. For this purpose, a diluted SS type is recommended. A light application of RC-70 or undiluted RS-1 or RS-2K will also serve satisfactorily as a tack coat.

4. Fog Seal - A very light spray application of emulsified asphalt, without cover aggregate, to an existing pavement as a seal to inhibit ravelling or enrich the surface. For this purpose, the SS types, diluted with water, are recommended.

5. Sand Seal - A spray application of asphalt on an existing surface, followed by a cover of sand to function as a seal coat.

   For hot climates, either MC-800, RC-800, RS-1 or RS-2K is recommended.

   For cool climates, RC-250 or MC-250 is recommended, although RS-1 or RS-2K will be satisfactory with adequate drying conditions.

6. Chip Seal - A spray application of asphalt on an existing surface, followed by a cover of rock chips or screenings to function as a seal coat.

   The asphalt used for chip seals must be fluid enough to wet and adhere to the chips and yet develop sufficient strength to retain the chips under fast traffic. RS-1, RS-2, or RS-3K are recommended for hot climates and good drying conditions. RC-3000, RS-2K, or RS-3K is recommended for cooler climates.

   If proper construction practice is followed, MC-3000 or paving asphalt 120/150 penetration grade may be successfully used in hot climates.

21343

11. Plant-Mixed Cold Laid - With well-graded aggregate having 4% to 10% passing the No. 200 sieve, SC-800 or MC-800 should be used in hot climates. In cool climates, MC-800 is recommended.

    This type of mix is normally prepared in a central mixing plant with the aggregate heated to some degree (see Table VIII) to produce a well-mixed product for use in light traffic areas.

    Central mixing plant base stabilization without heat can be done with SM-K or SS-Kh.

12. Patching Mix - Mixes prepared for maintenance patching, usually in a central plant, and occasionally by road-mixing methods.

    For mixes that are to be used immediately in hot climates, MC-800 or MC-250 is recommended. If immediate use is anticipated in cool climates, SC-800 or MC-250 is recommended.

    For mixes that are to be stockpiled before use, SC-250 or MC-250 is recommended. For patching mixes to be prepared by road-mixing methods or stockpiled for long periods before use, SC-250 is recommended.

13. Asphalt Concrete - This material is mixed in a central plant using heated aggregates of high quality and a paving grade asphalt. The mix is produced under close control and provides the highest type of asphalt pavement for any use.

    a. Industrial Floors - For this use, 40-50 penetration grade is recommended with a good quality aggregate having rough surface texture.

    b. Parking Areas - For parking lots and driveways in hot climates, 40-50 or 60-70 penetration grade is recommended. In cooler climates, 60-70 or 85-100 penetration grade should be used.

    c. Highways - Good Quality, Rough-Textured Aggregate. With good quality aggregates and in hot climates, 60-70 or 85-100 penetration grade is recommended. With the same type of aggregate in cool climates, 85-100 or 120-150 penetration grade should be used.

       With borderline quality aggregate, the use of 60-70 or 85-100 penetration grade is recommended.

21345

d. Airports - Good Quality, Rough-Textured Aggregate. In airport paving, 60-70 penetration grade is recommended in hot climates. In cool climates, 60-70 or 85-100 penetration grade should be used.

e. Curbs - For asphalt concrete to be used for curb construction, 40-50 or 60-70 penetration grade is recommended.

f. Open-Graded Surface Course - For open-graded mixes used as wearing courses, 60-70 or 85-100 penetration grade is recommended.

TABLE II
RECOMMENDED USES OF ASPHALT

(1) Diluted with water.

In northern areas where rate of curing is slower, a shift from MC to RC or from SC to MC may be desirable.

For very warm climates, a shift to next heavier grade may be warranted.

21346

Recommended Uses of Asphalt

The selection of the type and grade of asphalt for a particular use is influenced by several considerations. Some of the major factors to be considered are:

1. Type of construction, ranging from a dust palliative to an asphalt concrete pavement.

2. Conditions of usage after construction (type of loading, i.e., rolling or static; magnitude of loading, i.e., maximum gross loads and maximum unit loads; climatic conditions in the area of usage, i.e., hot, cold, wet)

3. Aggregates with which the asphalt will be used (gradation, soundness, absorptiveness, surface texture)

4. Method of construction and equipment available (mixing, spraying, central plant, mix in place, machine or hand-placing)

5. Climatic conditions during construction (temperature, humidity, wind).

In general, for cooler climates the softer, more fluid paving asphalts or the liquid asphalts having the more volatile solvents may be favored because of construction considerations. The reverse will frequently be true in hotter climates.

The viscosity of the asphalt that will be desirable after construction will be influenced by the gradation or the amount of fine particles in the aggregates used. This factor will also be influenced by the magnitude and type of loads that will be imposed and the climatic conditions under which the finished surface will be used. For example, aggregates deficient in fine particle sizes will require more viscous asphalts. The more viscous asphalts will also be desirable under high unit loads and in hot climates. The viscosity of the asphalt that can be properly handled during construction, however, will be determined by the method of construction and the equipment available.

Because of these factors and considerations, it is not uncommon and, in fact, is quite proper to use different types and grades of asphalt in different areas for the same type of work and for the same conditions of usage after construction.

Following is a brief discussion of the various types of construction with asphalt and the types and grades of asphalt recommended for use. The discussions should be used in conjunction with Table II "Recommended Uses of Asphalt."

1. Dust Palliative - A light application of asphalt to knit fine surface particles together to minimize their

21242

7. Slurry Seal - A slurry mixture of SS type emulsified asphalt, sand, and water applied to an existing surface and squeegeed into place to serve as a seal coat. Only slow-setting emulsions should be used.

8. Penetration Treatment - A surface treatment consisting of a spray application of liquid asphalt applied to an untreated granular roadway to form a light duty wearing course by penetrating the roadway material.

   The type and grade of asphalt should be selected to fit the climatic conditions and the gradations of the material in the roadway. For most conditions, SC-250 or MC-250 is recommended.

9. Penetration Macadam - This type of construction consists of placing a uniform layer of coarse, crushed aggregate to a thickness slightly greater than the maximum size of aggregate used, followed by a heavy spray application of asphalt. A second layer of stone of smaller maximum size and another spray application of asphalt follows.

   For most conditions, 85-100 or 120-150 penetration paving asphalt is recommended. RC-3000, RS-1, or RS-2K may also be used.

10. Mixed-in-Place - Mixed-in-place or road-mix asphalt construction may be used for surface or base courses. It utilizes operations and equipment that allows the asphalt to be incorporated with the aggregate on the roadbed.

    With an open-graded aggregate that is low in amounts passing the No. 8 and No. 200 sieves, MC-800 is recommended in hot climates. With the same aggregate in cool climates, RC-800 or RC-250 is recommended.

    With clean sand passing a No. 4 sieve but with small amounts passing the No. 200 sieve, RC-250, MC-250, SS-1h, SM-K, or SSKh are recommended in hot climates. With the same aggregate in cool climates, RC-250 or SM-K is recommended.

    With well-graded aggregate containing up to 15% passing the No. 200 sieve, SC-800, MC-800, SS-1h, SS-Kh, or SM-K are recommended in hot climates. With the same aggregate in cool climates, MC-250 is recommended.

    For stabilizing sandy soils having up to 20% passing the No. 200 sieve, SC-250, MC-250, SS-1, or SM-K should be used in hot climates with good drying conditions. With the same sandy soil, SC-250, MC-250, or SM-K should be used in cool climates.

NATIONAL BUREAU OF ST

DEPARTMENT OF TRANSPORTATION
FEDERAL AVIATION ADMINISTRATION
INSPECTION REMINDER

The next annual inspection of this aircraft required by Federal Aviation Regulations is due:

DATE 6/30/68

FAA Form 8320-2 (6-67)
Formerly FAA Form 2912
* GPO: 1967 OF—277-820

FIGURE 8.

AIs should issue FAA Form **8320-3 on completing annual** inspections. The form is issued regardless of airworthy or unairworthy findings. The date the next Annual Inspection is due will be the last day of the month, 12 months following the date of the inspection. AIs may receive a supply of these forms from the FAA field offices.

TION TEST CHART
STANDARDS-1963-A

V-B-3 Construction of Seal Coats

The surface upon which a seal coat is to be placed must be clean. This may be accomplished using paver brooms or other suitable equipment to remove dust and loose particles. If the seal coat is to be placed over a base it must first be primed, usually with RC or MC 70 and allowed to cure until all volatiles are evaporated. Wet spots (excess asphalt which has not penetrated) should be sanded to prevent pick up.

In any spray application of asphalt the temperature of the surface is critical. It is generally recommended that the surface temperature be above 80°F. to allow the asphalt to spread out and be fluid enough to wet the chips or penetrate the base in the case of a prime coat.

The asphalt used for seal coats must be capable of holding the chips in place after curing. There must also be enough to bury the chips to about 60% of their depth. The amount of asphalt to spray depends upon the gradation of the chips, the absorption of the surface on which the seal is to be placed and on the amount the chips may absorb.

Chips should be clean and slightly damp. They should be placed as soon as possible after the asphalt has been spread. The chips should be rolled with pneumatic or steel rollers, with pneumatic rollers being preferred. The rollers used for paving are generally suitable for rolling chips but should be unballasted; that is, heavy rollers are not necessary since the roller's function is to seal the chips in the asphalt.

For a more detailed discussion on surface treatments, the student is referred to the Asphalt Institute's Manual Series #13 "Asphalt Surface Treatments and Asphalt Penetration Macadam" available from any office of the Institute.

21353

UNIT V - PAVING

V-B-4 Road-Mix Surface Construction

Introduction

Mixed-in-place, or Road-mix, is an asphalt course produced by mixing aggregate and liquid asphalt at the roadsite by means of travel mixers, motor graders, or other road mixing equipment. The principal advantage of this type of construction is that it utilizes aggregate already on the site, or which is available from nearby sources. When using such materials, aggregate and asphalt can be mixed in place at low cost, with a minimum of equipment.

Road-mix may be used for surface, base, or subbase courses if the pavement structure is designed properly. As a surface course, it is suitable for medium and light traffic. For base or subbase, it is suitable for all types of traffic. It has special advantages for outlying areas; long stretches of farm, desert, or ranch roads; detours; and other locations where an economic problem exists in getting the necessary improved mileage. It is seldom used in urban and other heavy traffic areas.

Some significant factors in road-mix construction are:

1. Suitability for stage construction. By road-mix methods the pavement structure can (a) be designed and built to meet current traffic requirements, and (b) be increased to thicknesses dictated by subsequent traffic by the laying of additional courses.

2. Weather. To facilitate evaporation of moisture and volatiles from the mixture the weather should be hot and dry. Extra manipulation is required to remove volatiles in cool and humid conditions. Work should be suspended during wet weather.

3. Versatility. A number of types and grades of asphalt are available that will satisfy the varying requirements of different aggregate and weather conditions.

4. Economy. Road-mix is economical because of the high production rates possible with a comparatively low investment in equipment.

Consideration (4) applies especially to mixing with motor graders and rotary tine mixers. Travel mixers, other than the rotary tine type, fall in an intermediate category--both as to economics and quality or operation--between motor graders and central plant mixers.

Aggregate

A wide variety of aggregates and soil-aggregate combinations can be processed satisfactorily by mixed-in-place methods. Surface course

21354

3. The uniformity of the gradation of the material and volume of the windrow must be controlled.

4. The proper amount of asphalt must be determined and applied.

In performing this type of work, the mixing machine moves along the windrow adding asphalt as it goes. If the windrow is so large that all of the asphalt cannot be incorporated in one mixing pass, it should be split into two or more windrows and the asphalt added to each in one mixing pass. Further mixing of the windrowed material after the addition of the asphalt may be necessary. Unless the travel mixer can be used as a multiple pass mixer this additional mixing usually is done with a motor grader; this makes sure that all the windrowed material is incorporated into the mix, and it also aerates the mixture for the removal of moisture and volatiles. The number of passes with the motor grader required for this purpose varies with different job conditions. However, in general a minimum five or six passes are necessary. After the mixing and aeration procedure has been completed, the windrow should be moved to one side of the area to be surfaced in preparation for spreading.

A different type of travel plant operates by mixing asphalt and aggregate deposited directly into the plant's hopper by truck; it then spreads the mix in one pass. Except when using open graded mixtures, in this technique care must be taken to insure sufficient evaporation of moisture and volatiles from the spread mix prior to compaction.

The rotary type of travel plant combines the asphalt and aggregate under a hood by means of whirling tines or blades as the machine moves over the surface. Most of these machines are now equipped with a spray system which applies the asphalt while mixing. When using this rotary type of mixer the following steps are recommended:

1. Spread the aggregate to uniform grade and cross section with motor graders.

2. Thoroughly mix the aggregate by one or more passes of the mixer. When ready for the asphalt the moisture content of the aggregate should not exceed 3 per cent, unless laboratory tests indicate that a higher moixture content will not be harmful when the asphalt is added.

3. Add asphalt in increments of about 0.5 gallon per square yard until the total required amount of asphalt is applied and mixed-in. A total of 0.4 to 0.6 gallons per square yard per inch of compacted thickness of the course is usually necessary. If the mixer is not equipped with spray bars the asphalt may be applied with an asphalt distributor.

21362

4. Make one or more passes of the mixer between applications of asphalt, as necessary to thoroughly mix it in.

5. Maintain the surface true to grade and cross section by using a motor grader during the mixing operations.

6. Aerate the mixture by additional manipulation, if needed.

For blade mixing the material should be placed in the windrow either through a spreader box or by running through a windrow sizer prior to the addition of asphalt. The proper percentage of asphalt for the aggregate in the windrow must be determined, and the amount needed per lineal foot of windrow calculated. Non-uniformity of grading of the aggregate in the windrow will cause a fluctuation in the asphalt demand, and this should be avoided.

The asphalt is applied to the flattened windrow from a distributor truck. Best results are obtained by adding asphalt to aggregate in multiple applications and by folding the asphalt into the windrow immediately behind the distributor truck.

NOTE: Where a pavement surface is available it can be utilized as a mixing platform--the mix being windrowed on it and later moved to the place of use. This practice is most often followed in the preparation of maintenance mixtures.

As the mixing progresses close attention should be given to uniformity of the mix in the windrow--the mixing of the material in the windrow should continue until all aggregate particles are uniformly coated. During mixing, attention should be paid to the vertical and horizontal angles of the mold board of the grader; this board should be adjusted so that a complete rolling action of the material is obtained when the windrow is manipulated. Also, during mixing, care must be exercised in order that extra material is not taken from the mixing table and incorporated into the windrow. At the same time, none of the windrow should be lost over the edge of, or left on, the mixing table. After mixing and aeration are complete, the windrow should be moved to one side of the area to be surfaced in preparation for spreading.

NOTE: When skilled operators are not available, trouble is sometimes encountered in controlling the depth of mixing of a road mix made on the roadbed. An unskilled operator may pick up additional material and thus dilute the mix; or conversely, drop out some of the mix material and produce a layer which is too thin and over-asphalted.

21363

21352

c. The travel plant mixer that takes the aggregate from windrows, mixes it with the asphalt and usually deposits the mixture in a windrow behind, ready for spreading and aerating by motor graders.

3. The water distributor that is used to dampen the aggregate.

4. The asphalt distributor that is used to apply the asphalt when the mixer is not equipped to do so.

5. Rollers, self-propelled steel-wheeled tandem and pneumatic-tired, used to compact mixes.

6. Asphalt tank trucks, dump trucks, power brooms, windrow sizers, and other auxiliary equipment.

Proportioning of Materials

The amount of asphalt for mixed-in-place can be determined by one of the following methods:

1. "Method of Testing Soil-Bituminous Mixtures," ASTM Designation D 915; "Methods of Test for Resistance to Deformation and Cohesion of Bituminous Mixtures by Means of Hveem Apparatus," ASTM Designation D 1560; "Method for Preparation of Test Specimens of Bituminous Mixtures by Means of California Kneading Compactor," ASTM Designation D 1561; and the Centrifuge Kerosene Equivalent (CKE) Method.

2. Where the laboratory equipment required in the above methods is not available, one of the following formulas may be used:

FORMULA No. 1

Formula for Determination of Estimated Per Cent RC, MC, and SC Asphalt Requirement

$$p = 0.02a + 0.07b + 0.15c + 0.20d$$

Where p = Per cent* of asphalt material by weight of dry aggregate

a = Per cent* of mineral aggregate retained on No. 50 sieve

b = Per cent* of mineral aggregate passing No. 50 and retained on No. 100 sieve

c = Per cent* of mineral aggregate passing No. 100 and retained on No. 200 sieve

d = Per cent* of mineral aggregate passing the No. 200 sieve.

Absorptive aggregates--such as slag, limerock, vesicular lava and coral--will require additional asphalt.

 21357

FORMULA No. 2

Formula for Determination of Estimated Per Cent Asphalt Emulsion Requirement

$$P = 0.05A + 0.1B + 0.5C$$

Where P = Per cent* by weight asphalt emulsion, based on weight of graded mineral aggregate

A = Per cent* of mineral aggregate retained on No. 8 sieve

B = Per cent* of mineral aggregate passing No. 8 sieve, retained on No. 200 sieve

C = Per cent* of mineral aggregate passing No. 200 sieve.

* Expressed as a whole number.

Construction

Prior to road-mixing operations, the roadbed on which the mixed material is to be placed must be shaped and compacted. A prime coat should be applied and allowed to cure. Where the prime coat does not penetrate, the excess asphalt should be blotted with sand.

A check should be made of all drainage facilities. Any that are not functioning properly should be corrected before road-mixing operations begin.

In several types of road-mix construction it is necessary to place the aggregate into windrows. Windrow sizers should be used to insure the placing of the correct volume for the desired depth of pavement.

Usually, loose material on the road surface is in too small quantity and is not uniform enough for worthwhile use in the road mix. In such a case it is more economical to blade the loose material on to the shoulders rather than perform the several operations necessary to blend it with the imported material.

However, if it is practical to use material from the road surface in the mixture, it should first be bladed into a windrow and measured. This material should then be made to conform to grading specifications by the addition of other aggregate, if necessary. Finally, imported material meeting the specifications should be added to the windrow to provide the required volume. If two or more materials are to be combined on the area to be surfaced, each should be placed in its own windrow. These windrows should then be mixed together thoroughly before the asphalt is added.

A method of determining the quantity of material in a windrow is illustrated in Figure 1.

21358

To calculate the quantity of aggregate in cubic feet per lineal foot of windrow:

Take measurements "A," "B," and "C."*

Then, ("A" × "B" × 1 ft.) + ("C" × "B" × 1 ft.) = cubic feet of windrowed aggregate per lineal foot.

* Note: If measurement "C" is not the same on both sides of windrow, use the average measurement.

Figure 1 - Volume of Windrows

Asphalt is added to the aggregate from an asphalt distributor or from a travel mixer. Whichever method is used, close control of the quantity and viscosity of asphalt applied is necessary to insure a proper mixture. Proper viscosity is essential, for the asphalt must be fluid enough to flow easily through the spray nozzles and to adequately coat the aggregate particles. Liquid asphalts, although already fluid, need some heating to bring them to the proper viscosity for spraying. But, unless mixing begins immediately after the asphalt is sprayed, the viscosity will quickly rise above that recommended for mixing. The volatiles in liquid asphalts keep them fluid long enough for completion of road mixing if it is done promptly. Mixing will take place at the temperature of the aggregate, but aggregate temperatures below 50° F. or above the temperature of the liquid asphalt should not be permitted. Figure 2 and Table 1 can be used to determine the range of temperatures for the proper spraying and mixing viscosities of liquid asphalts.

21359

TABLE 1

MIXING AND SPRAYING TEMPERATURES FOR VARIOUS GRADES OF ASPHALT EMULSIONS*

Type and Grade	Suggested Temperature	
	For Mixing**	For Spraying#
Anionic		
SS-1	75-130°F	75-130°F
SS-1h	75-130°F	75-130°F
Cationic		
SM-K	100-160°F	100-160°F
SS-K	75-130°F	75-130°F
SS-Kh	75-130°F	75-130°F

* Since the working temperature range for emulsions is comparatively low and is based only on that temperature necessary to provide a viscosity at which they can be dispersed through spray nozzles, the same temperature is specified for spraying and mixing. Mixing will take place at the temperature of the aggregate, but aggregate temperatures below 50°F. or above the temperature of the liquid asphalt should not be permitted.

** Temperatures based on 75-150 seconds Saybolt Furol viscosity.

Temperatures based on 25-100 seconds Saybolt Furol viscosity.

(3) There is no stigma attached to the aircraft because it was reported as "unairworthy." In effect, the report says the aircraft is airworthy with the exception of the items on the discrepancy list. When those listed items are corrected, the aircraft is eligible to be operated.

j. Incomplete Inspection. In the event the annual inspection is not entirely completed, the AI:

(1) Should indicate in the aircraft records any discrepancies he has found.

(2) Should NOT indicate that an annual inspection was conducted.

(3) Will not forward the inspection report FAA Form 8320-2.

8. MAINTENANCE RECORDS. The AI and other maintenance personnel or agencies are required to record maintenance, inspections, or alterations that they perform or approve in accordance with the requirements of FAR 43.9 and 43.11. FAR 91.173 requires the owner/operator to keep maintenance records and to present them each time an inspection, repair, or alteration is performed. He is also required to indicate the time in service when the work is done. See Figures 9 and 10 for typical entries used by AIs.

a. Significance of Maintenance Record Entries. Responsibility for maintenance performed rests with the person who enters his name on the appropriate maintenance records and/or forms. The responsibility for annual and progressive inspections and for approval and return to service of major repairs or alterations is assumed by the AI whose signature appears on the appropriate maintenance records.

b. Completion of FAA Form 337 by AIs. See Figure 11. The FAA Form 337 serves two purposes; one is to provide owners/operators with a record of major repairs and alterations indicating details and approval, and the other is to provide the FAA with a copy for the records. The FAA copy of FAA Form 337 is retained by the Agency's Data Services Division, AC-300, P.O. Box 25082, Oklahoma City, Oklahoma 73125. Copies of these forms may be obtained for established fees.

(1) The person who performed or supervised the repair or alteration prepares the original FAA Form 337 (two copies). The AI then further processes the forms when they are presented to him for approval.

(2) The official instructions for the completion of the form appear in AC 43.9-1B, or subsequent revisions.

c. Disposition of FAA Form 337.

(1) After the AI has found the alteration or repair to be in accordance with FAA-approved data, reviewed the FAA Form 337 for completeness, and completed item 7, he:

SITS 2111

construction normally requires higher quality aggregates than do base and subbase construction.

Commercially crushed stone, slag, and gravel are widely available for mixing-in-place. There are also many localities where it is economical to crush aggregate from road cuts, pits, or nearby quarry sites. Crusher run material with from 0 to 10 per cent passing a U. S. Standard No. 200 sieve, up to a maximum size of two inches, or two-thirds of the course thickness, whichever is smaller, usually proves excellent for mixed-in-place bases. Generally, the entire output of the crusher that is below the specified maximum size may be used in the asphalt pavement structure. This affords maximum economy.

Suitable local materials range all the way from granular soils with up to 25 per cent passing a No. 200 sieve, liquid limit up to 30 and P.I. up to 6, through the range of clean sands and gravels. Higher limits, proved by experience, can be used for some aggregates. With these finer gradations, however, mixing, aeration and compaction problems may be encountered. On many projects, by careful selection, suitable materials for road-mix courses may be obtained from excavation or borrow. On other sites, materials may be available within or adjacent to the right-of-way either as they are in the pits, by blending different strata or areas of the pits, or by blending with other materials at the pit or on the road. Well-graded aggregates are always desirable for any course of the asphalt pavement structure, but many poorly graded and gap-graded aggregates have proven adequate for base course road mixes when combined with the proper asphalt in accordance with good construction procedures.

The suitability of road-mix materials can be determined by the various tests now utilized by state highway departments and other road-building agencies.

Asphalt

The types and grades of asphalt for use in road-mix construction are determined by the characteristics of the aggregate, type of road mixing equipment to be used, and climatic conditions. Generally, types and grades of asphalt used are as follows:

1. Open-graded aggregate

   a. Rapid and medium curing liquid asphalts RC-250, RC-800 and MC-800.

2. Well-graded aggregate with little or no fine aggregate and material passing the 200 sieve

   a. Rapid and medium-curing liquid asphalts RC-250, RC-800, MC-250 and MC-800.

21355

b. Slow-curing liquid asphalt SC-800.

c. Slow-setting asphalt emulsions, SM-K, SS-1, SS-1h, SS-K and SS-Kh.

3. Aggregate containing a considerable percentage of fine aggregate and material passing the 200 sieve

a. Medium-curing liquid asphalt, MC-250.

b. Slow-curing liquid asphalts, SC-250 and SC-800.

c. Slow-setting asphalt emulsions, SS-1 and SS-K.

Asphalt emulsions are often used with damp aggregate. Very dry aggregate with considerable fines may require dampening with water before emulsions are applied.

Equipment for Mixed-in-Place Construction

Equipment for road-mix constructions falls into the following principal categories:

1. Motor graders.

2. Three types of travel mixers that employ rotary tines or blades: (a) the pulverizer type that mixes in place and (b) and (c) types that are intermediate between the pulverizer type and the stationary asphalt plant--see below for details. The latter two contain many of the parts found in the usual asphalt plant with the exception of dryer and screens.

a. The rotary pulverizer-type mixer with transverse shafts that mix the asphalt and aggregate with revolving tines under a hood. Most makes have only one rotor but some have up to four rotors, all under a long hood. Many are now equipped with a spray system which applies the asphalt, and water if needed, while mixing.

b. The travel plant mixer that receives the aggregate into a hopper from trucks, mixes it with asphalt, and spreads the mixture--all in one pass of the machine.

21356

Figure -2—Temperature-Viscosity of Liquid Asphalts

Kinematic viscosity, centistokes = $\frac{\text{Absolute viscosity, centipoises}}{\text{density}}$

Saybolt Furol viscosity $\simeq$ 0.5 centistokes viscosity

An advantage of travel-plant mixing is that closer control of the mixing operations can be achieved. The proportioning of the asphalt with the material, as well as the uniformity with which the two can be incorporated, are of the greatest importance. However, in order to achieve a uniform product it is necessary that several precautions be taken:

1. The road-mixing machine must be in satisfactory operating condition.

2. A windrow of prepared material must be established.

21361

resistant and light-reflecting properties. If a burlap drag is used, it should be at least 3 ft. wide and long enough to cover the entire lane width. The burlap is pulled forward in such a manner that at least 1 ft. of the burlap is in contact with the pavement surface. If the burlap is kept wet and free from hardened mortar a sandpaper-like texture will result-an attractive texture that is highly skid-resistant. Either type of surface finish must be produced after the water sheen has disappeared from the surface and before the concrete has hardened too much to permit good finishing.

JOINTS

LONGITUDINAL JOINTS

Longitudinal construction joints of the tongue-and-groove type must be provided between construction lanes. The joints are formed in the slab edge by attaching to the side forms a metal or wooden keyway form of the desired shape and dimensions. If wooden keyway forms are used they must be maintained in good condition and well oiled before each use.

Generally, in order to control cracking, lane widths should not exceed 12 feet, and in thin slabs, 10 feet or less may be desireable.

CONTRACTION JOINTS

Transverse contraction joints in the slab will generally be spaced at relatively short intervals. Contraction joints may be one of three different types: sawed, formed dummy grooves or premolded strips. The depth of all joints regardless of type must be at least one-fourth of the slab thickness in order to properly control cracking.

Sawed joints are made by sawing a groove in the hardened concrete with a concrete saw after the concrete has gained sufficient strength to prevent ravelling of the joint during sawing. Sawing must be completed as soon as possible after paving, usually within the first 24 hours and often the same day the concrete is placed. If sawing is delayed too long, cracks may develop in the slab because of shrinkage of the concrete. If a diamond saw blade is used, it must be cooled with water to facilitate sawing. An abrasive blade

may be used wet or dry.

A contraction joint of the surface-groove type is formed in the plastic concrete by impressing a T-shaped bar into the surface, either by means of plow handles attached to each end of the bar or by a special joint-cutting machine that rides on the side forms. A metal or wooden templet of desired dimensions is then placed in the groove to prevent slumping of the concrete before some degree of stiffness is obtained. This templet must be removed from the joint before the concrete has completely hardened and the joint must be edged to remove sharp corners that might break off under traffic. The templet must be cleaned and oiled after each use to facilitate removal.

The third type of joint is a premolded bituminous strip embedded in the slab flush with the surface. The strip, which is inserted in a groove formed in the plastic concrete, must be vertical and continuous from slab edge to slab edge and through integral curbs. The joint must be edged in curb sections to prevent spalling of adjacent concrete. Care must be taken that the strips are not bent or tipped out of vertical by final surface finishing operations.

Contraction joints-sawed, surface groove, or premolded strips-are intended to reduce the slab cross-section at given points so that contraction stresses in the concrete will result in cracking at the joint instead of elsewhere in the slab. Joints must be formed with care or spalling will develop at these locations.

The contraction joint must be carried through adjacent curb sections. It should be sawed, formed and edged to match the joint in the pavement.

Transverse joints generally should not exceed 15 feet.

EXPANSION JOINTS

Expansion joints are sometimes provided at intersections and other special locations to reduce compressive stresses that may develop because of expansion of the concrete. Expansion joints usually consist of a filler of nonextruding bituminously treated fiber or a wooden board. Wooden boards must be free of knots. These fillers must be continuous from slab edge to slab edge and through curbs or curb and gutter sections, and they must be vertical through the full depth of concrete if they are to function properly as expansion joints. Any plug or sliver of concrete that extends over, under, through, around or between sections of the joint filler will cause spalling of the concrete. Usually fillers are held in place by stakes

in the sub-grade that are removed after the concrete is placed but before final finishing. The fillers are installed with the top about 3/4 in. to 1 in. below the surface and a groove is cut in the concrete immediately above the filer for sealing. It is of great importance that the groove is the same width as the filler and that no concrete overhangs the filler on either side.

CURBS AND
CURB AND GUTTER

The construction of curbs and of curb and gutter is covered in detail in the publication, Concrete Curbs and Gutters.* If integral curb is specified, the concrete for it should be left against a high outside form during screeding of the surface or brought from the mixer and deposited immediately after screeding so that bond to the slab will be ensured. If a rolled curb is called for, it can usually be built without any face form, the curb being shaped by use of a specially shaped mule or by the use of a straightedge and templets. If a straight-faced curb is specified, a special form will have to be attached to the outside form to permit construction. Curbs of this type require vibration in order to prevent honeycombing and ensure a dense curb face. Two-course construction should not be necessary to obtain good-looking concrete curbs if the concrete is vibrated or spaded in the curb forms. In integral curb pavement the transverse joints must extend entirely through the curb at the same location as the joints in the pavement. If a separate curb and gutter is used there should be joints in the curb and gutter opposite the joints in the slab, even though there may be intermediate joints in the curb and gutter.

The drainage of the gutter, whether integral curb or separate curb and gutter, should be checked while the concrete is still plastic by pouring water at the high point of the grade and observing its flow to the nearest catch basin. The concrete surface will not be damaged if the water is poured from a bucket onto a piece of burlap or curing paper. Such a check at this time will allow correction of any high or low spots detected by this test. This will eliminate "bird baths" or puddles in the gutter line of the pavement.

CURING

All concrete must be cured in order to ensure proper

* See Appendix A.

STRUCTURAL SERIES #2

CONCRETE PAVING

V-C-1 STREETS, PARKING AREAS, WALKS AND OTHER FLATWORK

The rules for obtaining and constructing quality concrete work outlined in Structural Series #1 also apply to paving work.

Probably the major distinguishing feature of paving as opposed to floors and similar types of flatwork is the method of finishing. Generally, paving serves to support people and vehicles out-of-doors. For good skid resistance in all types of weather, a rougher surface texture is required than for inside floors. Therefore, except for special conditions, steel-troweling is not required. The finishing process consists of striking off, floating at the proper time and texturing. These sequences can usually be accomplished in a shorter time than when troweling is necessary. For some special finishes, steel-troweling may be desired.

The following general description of construction procedures will apply to most outside flatwork.

SPECIFICATIONS

The materials and construction methods used must comply with all requirements of the specifications, and the pavement must be built according to the plans. Inspectors and contractors' representatives must be familiar with the plans and specifications. They must be alert and attentive throughout all construction operations to see that all pavement is built to meet the specification requirements in every detail.

SUBGRADE PREPARATION

The subgrade for concrete pavement should be uniformly compacted so that no soft spots are present. To obtain such results the subgrade soil should be compacted at or slightly above the optimum moisture content. In the absence of standard testing, a reasonable evaluation of moisture content may be made by squeezing a ball

of damp soil in the hand. If the ball is so dry that it crumbles easily, additional water should be added. If it is so wet that free water comes to the surface when kneaded, the subgrade should be permitted to dry before final rolling. If there is free water standing on the subgrade in puddles, the subgrade must be permitted to dry before placing concrete.

The subgrade can be compacted with a flat steel-wheel roller of adequate weight or with a rubber-tire wobbly-wheel roller. Special care must be taken in the compaction of backfill of sewers and around manholes and other permanent structures in the paved area. This can be done best by use of some type of vibratory compacter that is small enough to operate within the limited area.

If the plans call for a layer of granular subbase under the pavement, the material used should comply with specifications and should be uniformly spread and compacted to the specified thickness and density.

Both subgrade and subbase should be checked before paving to see that there are no puddles,soft spots or frozen soil. Any such areas should be corrected and, if necessary, the subgrade should be removed and replaced with suitable material before concrete is placed.

FORMS

Either wood or steel forms may be used. Forms that are bent, have battered top surfaces of defective fasterners, or are otherwise defective should be removed from the job and not be returned until careful inspection shows them to have been adequately repaired.

Forms should be carefully set to the required line and grade to ensure both a smooth-riding surface and proper drainage of surface water. They should be placed on firm, properly compacted subgrade, not on loose, unconsolidated material. All forms must be firmly staked to prevent movement during paving operations. This will require at least three form pins for each 10-ft. length of form. The distance between the side forms should be checked to see that the specified width of paving lane is provided. All forms should be oiled before placing concrete and cleaned after each use.

Forms must remain in place at least 12 hours after

the concrete has been placed. Great care should be exercised in removal of the forms to prevent damage to the concrete. Bars or heavy tools should not be used to pry against concrete during form removal.

FINE GRADING

After the forms have been set and staked, the subgrade between the forms should be graded with a suitable planer. This may be a motor patrol grader or a planer of some type that rides on the side forms. It should be set to cut the subgrade to the desired cross-section. After this final grading any loose material should be recompacted by rolling or tamping and the eveva-tion of the subgrade should be checked with a scratch templet. This is a series of spikes that projects down to the correct subgrade level from a bridge spanning the space between the forms. The templet should be checked often to avoid error from sagging and warping.

Just before paving, the subgrade should be uniformly dampened to prevent it from absorbing water from the concrete mix. On projects where concrete is placed from ready-mix trucks, sprinkling can be done with a hose from the water tank on the truck.

PAVING WITH QUALITY CONCRETE

PROPORTIONING AND TESTING

The concrete should be proportioned at a batch plant equipped with properly calibrated scales to ensure that all batches contain required cement content and specified weight of fine and coarse aggregate. Frequent checks should also be made of the water meter on the paver or ready-mix trucks to ensure that the water content does not exceed the amount specified. The concrete mix should be such that the slump as measured in a standard slump cone does not exceed 4 in. for hand-finishing methods or about 2 in. for machine-finished concrete. A Kelly ball may be used instead of a slump cone, in which case it should be correlated with the slump cone for any given concrete mix to ensure proper consistency.

On all projects where snow, ice and freezing temperatures will be encountered, it is essential to use air-entrained concrete

for maximum durability. It is frequently used in other areas of the country because of the improvement in workability. When air-entrained concrete is used occasional checks of the plastic concrete should be made to ensure that the required amount of air (3 to 7 per cent is usually specified, but special conditions may require a higher air content) is present in each batch. For field inspections the pocket air indicator provides an easy method of determining the approximate air content. If the air content is not within the specified range, corrections should be made in the mix design to obtain the right amount of air. Dispensers for air-entraining agents must be inspected frequently to make sure that they are functioning property and dispensing the agent in the right proportion.

TRANSPORTING AND MIXING

Ready-mix trucks should be inspected before use to be sure that mixing time and speed comply with specifications. All concrete mixers should be checked to see that blade wear is not excessive and that mixing is uniform from batch to batch.

The importance of maintaining uniform consistency of the concrete from batch to batch cannot be overemphasized. Without uniformity good pavement quality, drainage and riding qualities cannot be attained.

PLACING

The concrete should be spread on the sub-grade by the paver or from a ready-mix truck as uniformly as possible to minimize the amount of additional spreading necessary. When concrete is being discharged from a ready-mix truck, it is important to have the discharge gate from the mixer wide open to prevent scalping of the large aggregate. Concrete may be spread with a mechanical spreader, shovels or a strike-off screed that rides on the side forms.

The process of spreading must also be accompanied by consolidation. Good dense concrete cannot be obtained by simply striking off level with the forms. Consolidation during spreading will ensure watertightness, high strength and durability. Uniform consolidation will also improve riding qualities.

Some special compaction is necessary along the side forms to prevent honeycombing and ensure good construction joints. This may be accomplished by the use of a vibrator along the forms or by hand-tamping with a shovel or special puddling tool. Such special

consolidation is also necessary at expansion joints or construction headers. Overvibration is to be avoided, especially of concrete having the higher slumps permitted with hand finishing.

FINISHING

Where mechanical finishing is used it is usually done with a two-screed finishing machine and, on the larger projects, with a mechanical longitudinal float. Before paving is begun these machines must be adjusted and checked as outlined in the manufacturer's instructions to ensure satisfactory operation in the consolidation, finishing and floating of the concrete. If mechanical finishing machines are not used, the concrete is usually struck off with a wooden screed in a sawing movement across the forms or with a vibrating screed that is pulled forward to strike off and consolidate the concrete. A vibrating screed pulled over the surface by two men can produce the desired results. In any case, a roll or head of concrete should be maintained ahead of the screed to ensure consolidation.

Following the screeding operation, use of a longitudinal float is necessary to remove surface irregularities and work up an adequate amount of mortor for proper finishing. If a mechanical longitudinal float is not used a manually operated wooden "bull" float is satisfactory. It should be operated with a longitudinal sawing motion while it is moved transversely across the slab by two operators standing on bridges that span the pavement. It is moved forward one-half its length after each transverse crossing of the slab.

Behind the longitudinal float the surface is given a final floating, if necessary, with long-handled floats approximately 4 ft. long and 8 in. wide. Following this operation the surface should be checked with a long handled 10-ft. straightedge to ensure a smooth-riding surface. The straightedge may be used with a scraping motion to remove any bumps and excess mortar from the surface, or it may be used to check evenness of the surface by placing it on the concrete at about 2-ft. intervals across the lane width. It should be advanced 5 ft. or one-half the length of the straightedge for successive checks.

After the surface has been floated and checked with the straightedge the concrete should be edged along the form and a final surface texture applied with either a broom or a burlap drag. The broom is used in a transverse direction across the lane to form uniform transverse ridges that will produce a surface with good skid-

21372

In graded granular aggregate mixtures the moisture and volatile contents are usually not highly critical. However, for maximum compaction, fine grained aggregate mixtures should be aerated to the required moisture and volatile content. Proper aeration is reached when the volatile content is reduced to about 50 per cent of that contained in the original asphalt and the moisture content does not exceed two per cent by weight of the total mixture (two to five per cent for emulsified asphalt mixtures).

When fine-grained materials are used as a base course that will be surfaced within 30 days, the volatile content of the asphalt should be reduced by aeration to approximately one-third of the original amount.

These values should be determined in accordance with the "Standard Method for Determination of Moisture or Volatile Distillates in Bituminous Mixtures," AASHO Designation T 110. Experience with the particular mixture being used and trial rolling are of value in determining the proper moisture and volatile contents when test data are not available.

Open-graded mixtures may be spread to the required depth and compacted with steel-wheeled tandem rollers and pneumatic-tired rollers immediately after mixing. The voids in the compacted open-graded mixture will allow the volatiles to evaporate in a reasonable length of time.

Well-graded and fine-grained mixtures are usually aerated before spreading. They are then placed in one or more windrows at the sides of the area to be paved. Motor graders are used to move material from the windrows, which is then spread in layers not exceeding four inches in depth. Compaction is done with pneumatic-tired rollers.

After one course is thoroughly compacted and cured, other courses may be placed on it. This operation should be repeated as many times as necessary to bring the road to proper crown and grade. For a smooth riding surface the motor grader should be used to trim and level as the rollers complete compaction of the upper layer. Any loose material that will not compact should be wasted over the sides.

Good weather is important to the success of a road-mix job. Road mixing operations should be scheduled for a time of year when weather conditions are likely to be hot and dry during, and for some weeks after, the work.

21264

January 18, 1967. Total aircraft time 853.00 hours, Tach reading 420.80. Replaced right main wheel bearing, P/N 19844, upper bushing in R & L landing gear frames, both brake hoses, P/N 34052, and bled brakes. I certify that this aircraft has been inspected in accordance with an annual inspection and was determined to be in airworthy condition.

Required entry for Annual Inspection when aircraft is found to be "unairworthy." Note that the date, total time, and tach reading are included.

HELPFUL HINTS

1. **Do not buck nature—stop operations when working under adverse weather conditions.**
2. **Keep the mixture or aggregate in a well-peaked windrow for better water shedding and control.**
3. **Provide drainage cuts through the windrow during heavy rains.**
4. **When a motor grader comes to the end of a section with a full blade, lift it rapidly to avoid carrying materials into the next section.**
5. **The distributor spray must be cut sharply at sectional joints; carry-over to the next section will cause undesirable fat joints.**
6. **Plan the work to avoid inconvenience to traffic.**
7. **Apply the asphalt at the recommended spraying viscosity to insure uniform application.**
8. **A shoe on the outer end of the motor grader blade or mold board helps obtain a good edge during spreading operations.**
9. **Aggregate in shaded areas usually requires extra aeration.**

UNIT V - PAVING

V-B-5 Constructing Asphalt Concrete Surfaces

This portion of Unit V - Paving is presented by using a text for the complete subject. The text is The Asphalt Institute's Manual Series No. 8 (MS-8) "Asphalt Paving Manual" available at any Institute office. This manual has been prepared for use by construction inspectors and others involved in asphalt paving.

The following is an outline of the text with supplementary notes to aid the instructor and students. It is suggested that at least two hours of classroom time be devoted to it and more if time is available:

Chapter I - Introduction

Chapter II - The Engineer and the Contractor

This chapter deals with pre-job planning. It discusses administrative matters, operations, equipment, procedures and timing of certain operations.

Chapter III - Preparation of Foundation for Asphalt Pavements

This chapter covers detailed procedures for preparing the underlying foundation for a surface. It includes compaction of granular bases, priming, preparation of old pavements, both flexible and rigid, cleaning old surfaces, etc. Some of the material duplicates that presented earlier.

Chapter IV - Inspection and Adjustment of Equipment

This is a rather thorough discussion of asphalt distributors, motor graders, windrow sizers, paving machines, rollers, hauling equipment and incidental tools from the inspector's standpoint.

Chapter V - Spreading

This chapter deals with mix inspection, spreading with motor graders, placing leveling wedges, paver spreading, automatic screed controls, hand spreading, joints and checking of the daily spread.

Chapter VI - Compaction

Rollers and their operation, sequence of rollers, rolling joints and compacting areas inaccessible to a roller are discussed.

21366

UNIT V - PAVING

Chapter VII - Shoulders

This chapter contains a short discussion on techniques of shoulder work.

Chapter VIII - Supplemental Work

Dike, curb, gutter, ditch and slope paving techniques are presented.

Chapter IX - Other Duties of the Inspector

Record keeping and house cleaning is discussed in this chapter.

strength gain and durability of the concrete. Curing prevents rapid loss of water from the mix and thus permits full hydration of the cement. It also helps maintain a relatively uniform temperature in the slab, preventing excessive volume changes that can cause cracking of the slab at an early age before the concrete gains adequate strength. If a wet-curing method such as the use of burlap, cotton mats or straw is specified, the curing medium must be kept wet for the entire curing period to ensure proper curing. If water-proofed paper or plastic film is used, it must cover the entire surface and edges of the slab and be free from rips, tears or holes that would permit moisture loss. If water-proofed curing membranes are used, they must be applied at the rate specified to ensure adequate coverage and they must be applied to the entire surface and pavement edge if they are to perform their intended function. White-pigmented membranes are preferred to clear membranes because they minimize temperature changes in the concrete and reduce early cracking. They must be well agitated before use to prevent settlement and to ensure uniform distribution of the pigment over the entire surface.

Regardless of the method used, curing must be applied early enough to prevent excessive moisture loss which could result in development of plastic shrinkage cracks. Usually curing can be applied as soon as the water sheen has left the surface and the final surface texture obtained with a broom or burlap drag. The curing medium should be left in place and properly maintained for the entire period called for in the specifications.

During periods of cold weather, paving operations must include special provisions to prevent freezing of subgrade or concrete. If freezing temperatures are expected, curing methods must provide for necessary slab protection.

OPENING TO TRAFFIC

The entire pavement area should be closed to all traffic during the period called for in the specifications, usually until about seven days after placement of the concrete unless a high-early-strength concrete is used. This traffic restriction applies to the contractor's construction equipment and vehicles as well as general traffic. Early traffic before the slab has gained adequate strength to support the loads can cause cracking of the new slab. Concrete pavers should never be allowed to operate on a completed slab.

Early and thorough cleanup of the job is an important responsibility of the contractor. As soon as curing and sealing are completed the slab should be cleaned of all debris and construction equipment. This will remove an objectionable eyesore to adjacent property owners.

SUMMARY

Failure to carry out specifications and follow good construction practices will result in a pavement that is unattractive, rough riding and lacking in strength and durability, a pavement that will not give the state, city, or adjacent property owner the return for his money which he has a right to expect. If all the operations outlined in this booklet are property carried out the resulting pavement will be attractive, smooth riding and durable.

APPENDIX B provides information on recommended practices of the construction of walks, driveways, floors and steps. APPENDIX C describes several methods of achieving interesting surface finishes. APPENDIX D is a slide talk covering simple low-cost methods and equipment for use in concrete street paving.

UNIT V - PAVING

APPENDIX A

CONCRETE CURBS AND GUTTERS

CONCRETE has become the standard material for curbs and gutters. Concrete combines good appearance with ample strength and reasonable cost. It permits the use of combined curb and gutter sections as well as various shapes and sizes of gutters and separate or integral curbs.

There are many types of curb and gutter construction, but the ones usually designed and built may be grouped into five general classifications:

1. Integral curb
2. Combined curb and gutter
3. Separate curb
4. Separate gutter
5. Lip curb

Curb Design

Certain principles of curb design are independent of the type of curb used. The height of the curb above the pavement, or curb exposure, depends on the established grades and on the quantity of water to be carried in the gutter. Usually, curbs should not be lower than about 4 in. and should not be high enough to damage fenders and bodies of cars parking on the adjoining pavement. If a height greater than 8 in. is necessary, some form of step curb should be used.

As a safety measure, curb radii should be sufficient to permit cars to enter or leave the street when making a right turn without interfering with traffic in other lanes. A radius of approximately 20 ft. will accomplish this. Smaller radii may be necessary at alleys or private drives, but they should approach this limit.

A curb with a sloping face and a well-rounded top edge is unlikely to damage tires. It encourages drivers to park close to the curb, adding to the effective width of the street. Curbs with a face in the shape of a reverse curve extending from the back of the curb to the gutter are easily shaped during construction and are attractive in appearance. When they are moderate in height with a fairly flat face they require no opening for driveways. This design is suitable for integral curbs or for combined curbs and gutters.

When sidewalks are to be built next to the curb or when an existing concrete walk abuts the curb, an expansion joint is placed between the curb and the sidewalk.

Integral Curb

This type is built as an integral part of the concrete slab. Besides performing the usual functions of a curb, the integral curb adds strength to the edge of the pavement and avoids a longitudinal joint between curb and pavement.

It is built, frequently without the use of a face form, by installing a supplementary back form. Fresh concrete is deposited against this back form and the front face is shaped by means of a special template or "mule."

A height of 4 to 6 in. and a base thickness of 8 to 12 in. are commonly used.

The only joints required in integral curbs are continuations of the transverse joints in the pavement. Dividing the curb into 6- to 10-ft. blocks is neither necessary nor desirable.

Combined Curb and Gutter

Combined curb and gutter designs are used on concrete-paved streets and frequently on unpaved streets or streets with surfaces other than concrete. When built to an established line and grade, they permit improvement of abutting property to proceed without fear of future change in alignment or gradient of the street.

The width of the gutter apron may range from 6 in. to an 8- or 10-ft. slab to provide a parking area where other types of pavement would be damaged by oil drippings or standing wheels, but the usual widths of the apron range from 12 to 36 in. While the curb may be

Integral curb may range from this flat rolling curb to one with an almost vertical face.

Drives built to meet top of sloping integral curb. It is not necessary to break out this type of curb when drives are built.

Top: Finishing machine rides on form for integral curb, and notched screed leaves proper amount of concrete to build curb.

Center: Shaping integral curb with a special tool called a "mule."

Bottom: Straightedging curb after shaping with a "mule."

of any height, 5 to 8 in. is the usual range. To encourage parking close to the curb, a sloping face and well-rounded edge are recommended. The slope of the apron should be a continuation of the regular street crown.

When built in conjunction with concrete pavement, expansion and contraction joints should be placed at the same locations as in the pavement slab. The curb and gutter should be tied to the pavement by ½-in. round deformed bars at about 3-ft. intervals. If no concrete pavement is being built at the time the curb is constructed, expansion joints should be placed at the ends of all returns and at intervals not to exceed 100 ft. Contraction joints should be installed at 15- to 20-ft. spacing.

The curb and gutter is often further divided into blocks by means of steel division plates used to maintain the correct relative positions of the front and back forms. The plates either fit into keys in wooden forms or are equipped with wings or lugs which fit into holes or slots in the top of either wooden or steel forms. They usually have two holes near their upper edge into which hooks may be inserted for withdrawing the plates as soon as the concrete is sufficiently hard.

Separate Curbs

Separate curbs are generally from 18 to 24 in. in overall height and 5 to 7 in. wide at the top, with the front face sloped to give a 6- to 10-in. width at the bottom. They should be jointed as described for combined curb and gutter. Separate curb is frequently built after the pavement is completed, which facilitates the construction of both the curb and the pavement.

Precast concrete curb is used to meet certain special job requirements or where it is convenient or desirable to cast it indoors during winter months. Dowels or tongue-and-groove joints are used to hold the separate blocks to line and grade.

Separate Gutters

Separate gutters are used to prevent erosion in shoulders or ditches. Concrete-paved gutters drain readily and therefore require a minimum of width and depth to handle a given volume of water. Many shapes are used, but the most common are those shaped like a V or the arc of a circle. When built adjoining the pavement, the side slopes and depth of a gutter and its outlets should be designed so as not to form a hazard to traffic in the adjacent lane.

Tiebars may be provided to hold gutter and pavement together, in which case joints in the pavement must be continuous across the gutter. Otherwise, they should be jointed as described for combined curb and gutter.

Lip Curb

Lip curb is really nothing but a very low, flat integral curb. Its use is confined to rural pavements in rolling country where its purpose is to prevent washing of channels in the shoulders. Lip curbs are constructed in a manner similar to that described for integral curbs. Usually from 2 to 4 in. high, they feather out in a width of 8 to 12 in.

No special joints are used, the transverse joints of the pavement being continued through the lip curbs.

Concrete for Curbs and Gutters

One-course construction is recommended for all types of curbs and gutters. A properly designed mix giving a workable concrete will result in a good finish without the use of a plaster coat. Such a workable mix can be produced by using a little less coarse aggregate for the same volume of sand and cement than is used in the pavement mixture. The maximum size of coarse aggregate should not exceed 1½ in.

The use of air-entrained concrete is recommended for the construction of concrete curbs and gutters in areas where there is severe frost action. It is needed where repeated application of sodium chloride, calcium chloride or granular materials impregnated with these salts is anticipated either on the gutters or on the adjacent pavements from which the salt solution will drain or be splashed onto the curbs and gutters.

21380

Combined curb and gutter is used on both paved and unpaved streets.

Curbs are sometimes built of white concrete since their high visibility gives them an important safety value. They are built like ordinary curbs except that white portland cement is used in place of normal portland cement. White aggregates are also used where available. Curbs of solid white concrete above the pavement grade have proved better than those with a facing of white mortar.

Condensed Specifications

Concrete shall consist of portland cement, fine and coarse aggregate and water. If air-entrained concrete is specified it shall contain 4 to 7 per cent air.*

Portland Cement and air-entraining agents shall comply with the requirements of the latest Standard Specifications of the American Society for Testing Materials.

Fine Aggregate shall be obtained from an approved source and shall consist of natural sand or an artificial sand having cubical particles produced from a durable coarse aggregate. It must be clean and well graded.

Coarse Aggregate may be gravel, crushed stone or air-cooled blast furnace slag. It must be clean, hard, durable, uncoated and free from deleterious material. It shall be well graded with no excess of any one size. All shall pass a 1½-in. sieve and not less than 95 per cent shall be retained on a ¼-in. screen.

---

* Air-entrained concrete may be obtained by the use of air-entraining portland cement Type IA, Type IIA or Type IIIA or by the use of Type I, Type II or Type III portland cement plus an air-entraining admixture.

Water suitable for drinking shall be considered satisfactory. Other water may be used only after analysis has proved it free from harmful materials.

Joint Filler shall be nonextrusive premolded material cut to the shape of the cross-section of the curb or curb and gutter. It shall be at least ½ in. thick or of the same thickness as that in the pavement.

Forms shall be of wood or steel of sufficient strength to resist the pressure of wet concrete. If of wood, they shall be of 2-in. material. When forming returns or curved sections, flexible strips may be used. The forms shall be held with suitable clamps and stakes to prevent movement or bulging when the concrete is being placed.

Division Plates for separate curb or for combined curb and gutter shall be of steel. They shall be of the correct size and shape and shall not be bent or otherwise deformed.

Subgrade shall be well drained and compacted to a firm surface having a uniform bearing power. It shall be wet down so as to be moist immediately before the concrete is placed.

Proportions shall be the same as those specified for the pavement if a concrete pavement is being constructed at the same time. Otherwise, a mix of approximately 94:204:306 by weight (for aggregates having a specific gravity of 2.65) or 1:2:3 by volume of dry, loose aggregate shall be used. The mixing water shall not exceed 5½ gal. per sack of cement, including the free water contained in the aggregates.

Mixing and Placing. The concrete shall be thoroughly mixed in an approved batch mixer for at least one minute

Left: Front form has been partly removed from separate curb to permit finishing.

Right: Spacer plates for sloping-face separate curb are held in place by notches in back form and plank along edge of pavement.

21381

Curb and gutter cross-sections are subject to wide variation in shape and dimensions. A few typical ones are shown here.

and shall have a consistency which will permit it to be worked readily into the forms. Usually a slump of not less than 2 in. nor more than 3 in. will be satisfactory. The concrete shall be placed promptly after mixing and in a manner to prevent any segregation of the mix. It shall be tamped and spaded sufficiently to bring the mortar to the surface and so that no honeycomb will be found when the forms are removed.

Finishing. The concrete shall be struck off true to cross-section, after which it shall be finished smooth and even by means of a woodfloat. Face forms, if used, shall be left in place until the concrete has hardened sufficiently so that they can be removed without injury to the curb. The exposed surfaces shall then be finished smooth and even by means of a moist woodfloat or a moist-wet brick. The remaining forms shall not be removed for at least 24 hours after the concrete has been placed.

The edges shall be rounded with an edging tool. No tool marks are to be left on exposed edges.

Before final finishing, gutters shall be tested with a 10-ft. straightedge to see that the finished gradient is uniform. Any depressions which will not drain shall be corrected.

Curing. As soon as possible without marring, the finished curb and gutters shall be covered with wet burlap, cotton mats, straw or earth and kept moist for a period of three days, or longer if directed. As an alternate, where practical, clear or white-pigmented membrane seal coats may be used, if, at the end of three days, they retain within the concrete at least 85 per cent of the original mixing water. In cold weather curbs and gutters shall be protected from freezing during the curing period.

Inspection. A competent inspector shall be present at all times while concrete is being placed. He shall see that forms for curb or curb and gutter are in alignment and are securely staked before concrete is placed. He shall check the proportions of concrete and, when it is placed, shall see that the concrete has the specified slump and air content. This will avoid segregation and insure adequate durability. If the slump is too great, it will be difficult to keep the face forms aligned and they must be kept in place longer to prevent the curb from slumping down. If the slump is too little, honeycomb and finishing difficulties may result. The best consistency will be one with which the concrete can be placed with a minimum of manipulation and yet result in uniformly dense concrete without honeycomb. In no case shall plastering of curb and gutter faces be permitted.

The inspector shall see that the curing and protection of the concrete is started as soon as possible and continued the required length of time.

UNIT V - PAVING

APPENDIX B

APPENDIX B

CONCRETE

SIDEWALKS DRIVEWAYS STEPS

176a 21384

SIDEWALKS

Well-constructed concrete sidewalks, driveways and steps increase property value and improve the appearance of the home. Properly built, they are durable, easy to keep clean, and provide many years of safe, dependable cost-free service. As a guide to insure quality concrete construction, a few simple rules are set forth in this bulletin.

LOCATION AND WIDTH

Where considerable pedestrian traffic is expected, sidewalks should be at least wide enough to allow two people walking abreast to pass a third person without crowding. A minimum width of 5 ft. is advisable and 6 ft. is preferred, as this width provides for convenient passage of two couples. A greater width should be used near schools, churches and other locations where walks are used by a great number of people.

In some neighborhoods sidewalks are built immediately adjacent to the curb. This type of construction gives the property owner a larger lawn and provides proper footing for people alighting from autos at the curb. However, sidewalks at this location give pedestrians less protection from street traffic.

TYPE AND DESIGN

At one time, almost all sidewalks were constructed in two layers—a base course and a wearing surface. Usual practice now is to build walks, driveways and garage floors with one-course construction. The full thickness of the concrete is placed at one time, and the same mixture is used throughout. Such construction is stronger and easier to build.

One-course residential walks should be not less than 4 in. thick. In business districts or shipping areas where sidewalks are required to resist the weight and impact of boxes dropped from trucks and wheeled into stores, the thickness should be a minimum of 6 in.

A slope of $^1/_8$ in. to the foot is sufficient to take care of surface drainage. The direction of slope will depend on local conditions but in general should be toward the curb.

Sidewalk design is very closely linked with street pavement and curb design. By coordinating the three, a pleasing effect may be obtained which adds to the appearance of the neighborhood. For the convenience of pedestrians, approaches at street crossings may be planned to do away with the step from street to sidewalk or to provide a low step over which baby carriages can be taken easily.

PREPARING THE SUBGRADE

The first step in construction is to prepare the subgrade. All sod and vegetable matter should be removed and any soft or mucky places must be dug out and filled with granular material, thoroughly tamped. Exceptionally hard, compact spots must be loosened and tamped to provide the same bearing power as the remainder of the subgrade.

When additional fills are required under walks to bring them to the proper grade, they should also be of a granular material thoroughly compacted in 6-in. layers. It is best to extend the top of all fills at least 1 ft. beyond the edges of the walk, and to make the slope flat enough to prevent undercutting during rains.

A well-compacted, well-drained subgrade does not require a specially prepared subbase. Subgrades which are water soaked much of the time should be provided with a 6-in. subbase of sand, gravel, crushed stone or cinders. Subbases must be drained to prevent the collection of water.

FORMS

Sidewalk forms may be of wood or metal. They must be staked so that they are held firmly to line and grade. The upper edge of the forms should be level with the finished grade of the walk and the forms should be oiled before the concrete is placed.

COPYRIGHT 1954 BY PORTLAND CEMENT ASSOCIATION

Fig. 4. Cleaning wooden strips.

Fig. 5. Removing joint forms.

Fig. 6. Filling joints with contrasting mortar.

The concrete may then be troweled for a normal gray color, or if desired, a different color can be added at this time.

To ensure uniformity of color, it is best to use a factory-prepared color topping. Color toppings consist of portland cement and fine aggregate in equal proportions, plus a pure mineral oxide pigment to produce the desired color. This pigment is an extremely fine powder and must be applied as a dry shake. Dry-shake color is thrown over the surface with a swinging arm motion. The powder is released between spread fingers; this breaks it up and produces a more uniform distribution. For best results, first spread out half the required amount, then float and trowel the surface before adding the second half.

After floating the second application, and before troweling, the top of the wood strips are cleaned of any paste that may have been carried over them. A patching trowel or putty knife can be used to scrape the wood clean (Fig. 4). A final steel-troweling will then bring the wood joints and concrete to a uniform surface, which can be left smooth or be lightly brushed.

The following day the curing cover can be taken off, and the wooden strips are removed by lifting with a patching trowel (Fig. 5). The slab may be left with depressed joints or with the joints filled in with a contrasting mortar. A natural gray slab with white mortar joints is very attractive; a colored slab looks good with natural gray joints.

Before filling the joints, the slab should be flooded with water to keep the slab cool and the joints damp. Immediately before troweling in the mortar, the

Fig. 7. Tooling joints in slab.

Fig. 8. Troweling after initial jointing.

Fig. 9. Touching up joints with soft brush.

joints should be brushed with a paste of portland cement and water, mixed to the consistency of heavy cream (Fig. 6). Care must be taken to prevent smearing mortar outside the joint area. A large coarse synthetic sponge and bucket of water will be useful in cleaning the joint edges. In this operation it is best for two finishers to work together, with one painting in the cement grout ahead of the mortar and cleaning up the joint edges, while the other concentrates on packing in the mortar firmly and neatly.

Alternate Method

An alternate method of producing the flagstone pattern involves tooling the joints into the surface. After the concrete has been screeded and darbied, and after excess moisture has left the surface, the slab is scored in a random flagstone design. This can be done with a jointer or groover; it is best, however, to use an 18-in.-long piece of ½- or ¾-in. copper pipe bent into a flat S-shape. This tooling must be done while the concrete is still very plastic, as coarse aggregate must be pushed aside by the tool and embedded into the slab (Fig. 7). The first jointing will leave burred edges. After the water sheen has disappeared, the entire area should be floated and the jointing tool run again to smooth the joints. A careful troweling follows (Fig. 8). The final operation is a light brushing of the troweled surface, along with a careful touching-up of the joints with a soft-bristle paint brush (Fig. 9).

Geometric Patterns

An attractive geometric pattern can be produced by marking circles or other designs on the slab after

MATERIALS

To insure quality concrete, the aggregate and water should be clean and mixed in proper proportions with portland cement. For sidewalks, driveways and garage floors, the recommended trial mix, when proportioned by volume, should be 1 part portland cement to 2¼ parts sand and 3 parts gravel or crushed stone. When proportioned by weight, the approximate amounts of fine and coarse aggregates recommended for one sack of cement are:

Pounds of Material

Portland cement	Sand	Coarse aggregate
94	215	295

(One sack of portland cement weighs 94 lbs.)

The gravel or crushed stone should be well graded in size between ¼ in. and 1 in. A mix proportioned by either of the above methods will usually produce 4½ cu.ft. of concrete for each bag of portland cement. Not more than 5 gal. of water per bag of cement should be used in mixing the concrete when the sand is in an average wet condition. Only enough water should be used to produce a concrete that works readily and does not segregate. Concrete with a slump of 3 in. or less, when tested with a standard slump cone, should be used and will permit proper placement.

If the recommended proportions do not make a smooth workable mix in the first trial batch, it may be necessary to vary the quantities of the sand and gravel or crushed stone slightly, but the amount of water should not be changed. The use of more mixing water than is recommended lessens the durability and reduces the strength of the concrete.

In northern climates where the concrete is subjected to freezing and thawing, air-entrained concrete is recommended. Air-entrained concrete can be made by using air-entraining portland cement or by adding an air-entraining agent at the mixer. The use of air-entraining cement is recommended for small jobs, or where adequate engineering supervision is not available to make determinations of the air content of the freshly mixed concrete.*

*On large jobs, where adequate engineering supervision is available, the method for obtaining air-entrained concrete should be that which best serves the users' interests.

SIDEWALKS

MIXING

Concrete made on the job should be mixed for a full minute after all the materials are in the drum. The drum should be completely emptied before receiving the materials for succeeding batches.

Ready-mixed concrete, used by many contractors, is generally available in most areas. When ordering ready-mixed concrete, it should be specified that aggregate used be not more than 1 in. in size with not less than 6 sacks of cement per cubic yard. The concrete should have a total water content of not more than 6 gal. per sack of cement and a slump of not more than 3 in.

Before the concrete is placed, the subgrade should be thoroughly dampened so that it is moist throughout, but without puddles of water. Concrete should be placed in the forms as near to its final position as practicable. Precaution should be taken not to overwork the concrete while it is still plastic because an excess of water and fine material will be brought to the surface, which may lead to scaling or dusting later on.

FINISHING

The concrete should be placed in the forms and tamped and spaded just enough to compact it firmly. Sidewalks should be finished with a slightly roughened surface to insure a safe foothold in wet weather. To obtain this, walks are finished with a wood float or are lightly broomed. After the concrete has been struck off, it is smoothed with a wood float or darby, leveling any raised spots and filling depressions. Side edges are then rounded with an edger to prevent chipping of the concrete. Where necessary, the marks left by the edges of the wood float may be removed by brushing with a calcimine brush dipped in water.

In some localities, the smooth finish obtained with a steel trowel is still preferred. When steel troweling is done it should be after all water sheen has disappeared and the concrete is so hard that no mortar accumulates on the trowel. This requires considerable effort on the part of the finisher to produce a satisfactory finish. Drawing the trowel over the surface of the concrete should produce a ringing sound. Excessive troweling is to be avoided as it tends to bring too much water and fine material to the top, forming a chalky surface.

Walks built on grades should have coarse surface texture, and steps should be built if the grade is steeper than 20 to 25 per cent.

SIDEWALKS

In sidewalk construction one form is set accurately to line and grade. Top edge of other form is determined with a level.

Forms in place for a 3-ft. wide sidewalk along curb. Driveway is already in place.

Strikeboard is used to level off concrete with a saw-like motion.

Long-handled wood floats or darbys are frequently used to smooth and level the concrete.

A small wood float produces an even, gritty, non-slip surface.

Outside edges of the walk are cut free f the side forms and expansion joints wit steel trowel.

JOINTS

Joints are placed in concrete sidewalks to take care of expansion and contraction caused by changes in temperature. There are two kinds of joints—expansion and contraction.

Contraction joints are simply separation planes between slabs. When the concrete shrinks in cold weather, these joints open slightly, thus preventing irregular and unsightly cracks. They are generally spaced at 5- to 6-ft. intervals.

Contraction joints may be formed by cutting a slot in the slab about 1 in. deep. This forms a plane of weakness and when the slab contracts, it will crack at this joint. The slot is cut by a T-bar forced into the fresh concrete for a depth of 1 in. After the concrete has partly hardened, the bar is withdrawn and the joint edged with a double edger held against a straight edge to make a clean, straight joint.

Expansion joints consist of premolded material usually ½ in. thick and as wide as the depth of the walk. They should be placed wherever the walk meets another walk, driveway, building, curb, lighting standard, fireplug or other rigid object. They are placed on all four sides of the square formed by the intersection of two walks. When the sidewalk fills the space between the curb and a building or wall, an expansion joint should be placed between the sidewalk and the curb and between the sidewalk and the building or wall. Expansion joints are not required at regular intervals in the sidewalk.

Fig. 11. Making leaf impressions.

Fig. 10. Making geometric patterns.

the final smooth finish has been completed. This can be done with a variety of sizes of tin cans in random pattern, or by one or more sizes in a definite regular pattern. Large metal cookie cutters of various shapes may also be used for this purpose.

Wherever a large area is to be finished in this fashion, several workmen will be required. Immediately after the final troweling, the surface will be quite hard but still easily marked (Fig. 10). However, as the slab continues to harden, it will become more and more difficult, and finally impossible, to make impressions to the same depth and appearance. In cases where more than one workman is involved, all must carefully coordinate their efforts so that the finished pattern will be uniform. A good method for determining the design to be followed is the production, on a nearby driveway or sidewalk, of a sample pattern. This is done by dipping the cans in powdered chalk and marking an area large enough to serve as a guide. The sample can easily be washed away later. If no slab is convenient, a large sheet of wallboard may be used.

Leaf Patterns

A pattern giving the effect of fossils can be produced by pressing leaves into the slab surface, either singly as a border, or in groups or sprays as a focus of interest. Fresh leaves are carefully pressed into the surface immediately after it has been floated and troweled (Fig. 11). The leaves should be so completely embedded that they may be troweled over without dislodging, but no mortar should be deposited over the leaves. After the concrete has set sufficiently, the leaves are removed.

Finishing Concrete Surfaces—

EXPOSED-AGGREGATE FINISHES FOR FLAT SLABS

Fig. 1. Selected aggregate is spread on darbied surface.

Fig. 2. Pressing aggregate beneath concrete surface.

Exposed aggregate is one of the most popular decorative finishes for flat concrete slabs. It offers unlimited color selection and a wide range of texture variation. Properly prepared exposed-aggregate finishes have a rugged nonskid surface that is highly resistant to wear and weather.

Selection of Aggregate

Things to consider in selecting decorative aggregate include size and color—to produce the desired effect; and shape and hardness—to produce a good-looking, long-lasting finish.

Size of the aggregate can vary from pea gravel to fist-size rocks, depending on the texture desired; the smaller the size, the finer the texture. Color can be a single uniform color, a mixture, or a random selection of hues, shades, and tones. In any case, aggregate chosen should be hard and sound. Flat, sliver-shaped particles, or aggregate that is too smoothly polished or ball-shaped should be avoided; such aggregates may not bond properly, are easily dislodged during exposing operations, and may be loosened, once exposed, by freezing and thawing. Aggregate should be cleaned prior to use. Aggregate normally used in concrete is dull in color, offers little variation in texture, and seldom gives satisfactory results for exposed finishes. Whatever aggregate is selected, a test panel should be made using it before the job is started. This will ensure that the material chosen will produce the desired finish.

Preparation

A 5½- to 6-bag concrete mix with a maximum slump of 3 in. should be used. Aggregate to be exposed should be cleaned and wet thoroughly before use to prevent mixing water being drawn from the concrete. Wetting also serves to lubricate the entry of the aggregate into the surface of the slab. After wetting, however, the aggregate must be drained to prevent free water being carried into the concrete.

Placing and Embedding Aggregate

Immediately after the slab has been screeded and darbied, the selected aggregate should be scattered by hand—evenly distributed so that the entire surface is completely covered with a single layer. Special care should be taken in covering the edge to ensure a uniform appearance (Fig. 1).

The initial embedding of the aggregate is usually done by patting with the darby or the flat side of the strike-off rod (Fig. 2). After the aggregate is

CURING

Concrete should be protected so that moisture is not lost during the early stages of hardening. Newly placed concrete should not be permitted to dry out too fast and must be protected from the sun or drying winds. This may be accomplished with burlap or canvas coverings which are kept wet. As soon as the concrete has hardened enough so that the surface will not be marred, the burlap or canvas can be removed, and earth, sand, or straw, kept moist by occasional sprinkling for three days, can be substituted. Sometimes watertight paper is used for such coverings. Membrane curing compounds sprayed on the surface of the concrete are often used to prevent evaporation of the moisture from the freshly placed concrete. These compounds should be applied immediately after the concrete has been finished.

COLD WEATHER CONCRETING

In cold weather the mixing water should be heated so that the concrete is between 50 and 70 deg. F. when it is placed. At no time should it be over 70 deg. F. In general, when outdoor temperatures are near freezing, the concrete should be protected by coverings of heavy paper and then with hay or straw, 10 to 12 in. deep, for the first three days after placing. Materials containing frost or ice should never be used in making concrete, and the concrete should never be placed on a frozen subgrade. The use of high-early-strength portland cement, the addition of calcium chloride (not more than 2 lb. per sack of cement), or the use of richer mixes when using Type I portland cement, will accelerate the hardening of the concrete and thus minimize the time protection is required.

SIDEWALKS

Applying a fine spray of membrane curing compound. Wet burlap or canvas may also be used for curing the concrete.

Sidewalk adjacent to curb at street intersection, showing low curb.

Hair broom drawn over concrete produces a slightly rough, gritty, non-skid surface.

lging tool is run along the edges of the walks d at expansion joints, rounding the edges prevent chipping.

Contraction joint grooves are sometimes cut with a steel trowel.

When edging contraction joints, a board is used as a guide to assure straight joints.

DRIVEWAYS AND GARAGE FLOORS

CONSTRUCTION

Concrete for driveways and garage floors is mixed, placed, finished and cured in the same manner as described for walks. If driveways are for residential use and subject to the occasional load of fuel or delivery trucks, they should have a minimum thickness of 4 in. Where they lead to stores or commercial buildings, the thickness should be at least 8 in. Garage floors should be at least 4 in. thick.

Driveways are usually constructed 8 to 10 ft. wide for single garages. When the approach to a two-car garage is short, the entire driveway is usually made double-width or about 16 ft. wide. On a long lot the driveway for a double garage may be widened near the garage so that cars can swing into either stall.

Some driveways are built with two strips for the car wheels. These strips are usually 24 in. wide and spaced about 5 ft. center to center.

If the sidewalks are constructed first, the driveway should be built with ½-in. premolded expansion joints placed on each side of the walk and where the driveway abuts the street pavement and garage. Frequently driveways are built before sidewalks. When this is done the driveway is placed directly from the street pavement to the garage with expansion joints at each end.

Contraction joints, similar to those described for sidewalks, should be placed in driveways at about 10-ft. intervals. Wide driveways for double garages should also have a center contraction joint to divide it into strips about 10 ft. wide.

The driveway, if built first, should meet the proposed sidewalk grade and rise gradually to the garage. From the sidewalk grade, the driveway should drop to meet the gutter grade where the curb is omitted, or to the top of any low-height curb.

Where the street is not paved it is advisable to end the driveway at the sidewalk. A temporary drive from the sidewalk to the street can be used until the street is paved. The driveway can be extended to the curb line at that time.

Concrete for driveways is struck off with a templet which shapes the surface with a crown or valley to insure proper drainage.

Edging contraction joints with double edger.

Fig. 3. Smoothing surface after aggregate is embedded.

Fig. 4. Floating to seal surface.

embedded, and as soon as the concrete will support the weight of a mason on kneeboards, the surface should be hand-floated with a magnesium float or darby (Fig. 3). This operation should be performed thoroughly, so that all aggregate is completely embedded just beneath the surface. The grout should completely surround and slightly cover all aggregate, with no holes or openings left in the surface (Fig. 4).

Following this floating, a reliable retarder may be sprayed or brushed on the surface according to the manufacturer's recommendations. On small jobs a retarder will probably not be necessary; retarders are generally used on large jobs for better control of exposing conditions. When a retarder has been used, exposure of the aggregate can generally be delayed. When a retarder has not been used, the aggregate must be exposed sooner.

Fig. 7. Slab after aggregate is exposed.

Fig. 5. Exposing aggregate by flushing and brushing.

Fig. 6. Touching up with hand brush.

Exposing the Aggregate

Proper timing is quite critical in exposing aggregate; a test panel should be made and tested to determine the best time to begin. Exposing should be done as soon as the grout can be removed by simultaneous brushing and flushing with water (Fig. 5 and 6) without overexposing or dislodging the aggregate. If it is necessary for masons to move about on the surface during exposing operations, kneeboards must be used with special care. If possible, this should be avoided because of the risk of breaking aggregate bond.

Curing

Exposed-aggregate slabs should be cured thoroughly. Care must be taken that the method of curing does not stain the surface. Straw, earth, and some types of building paper may cause staining.

Fig. 8. Sample panels show various aggregates.

Concrete is placed between the side forms and the fill.

Riser forms are checked with a hand level.

STEPS

FOOTINGS

Footings for the sidewalls for the steps should be placed on firm soil and below the frost line. The side walls should be tied in with the foundation walls with anchor bolts or tie rods. Often these footings are cast integrally with the basement walls.

FILLING

After the forms for the side walls are in place, cinders, crushed stone or gravel is used to make a fill before the concrete is placed. The fill should be well compacted by tamping. The concrete for the side walls is placed between the fill and the side forms and it too should be well compacted by tamping.

Riser forms are well braced.

The base course is tamped.

MEASURING MATERIALS

In building concrete steps, the concrete is usually placed in two layers—a base course and a wearing surface.

The base course should be composed of 1 part portland cement by volume to 2¼ parts sand and 3 parts gravel or crushed stone. Maximum size aggregate is limited to 1 in. Concrete should be mixed to a stiff, dry consistency, using only enough water to make it workable, and tamped into place. Concrete for the wearing surface, when proportioned by volume, should range from 1 part portland cement, 1½ parts sand and 1½ parts gravel or crushed stone to 1 part portland cement, 2 parts sand and 2 parts gravel or crushed stone. Maximum size of aggregate for the wearing surface should be ⅜ in. Not more than 4 gal. of water per sack of cement should be used in the mix for the wearing surface when the sand is in an average wet condition.

STEPS

FORMS

Forms for the risers should be carefully placed and checked with a hand level. The riser or step height should be about 7½ in., with treads either 9 or 10 in. in depth. For additional comfort in climbing, the face of the riser form can be tilted about 1 in., thereby increasing the width of the tread. The riser forms must be securely fastened to the side forms and well braced to prevent bending when the forms are filled with concrete.

PLACING

The dry-mixed concrete for the base course should be well tamped into place allowing a 1-in. space for the wearing surface. The wearing surface should be placed on all treads as soon as possible (within 45 minutes) to insure proper bond.

The riser forms can be removed one at a time, starting with the top riser, as the wearing surface is placed.

FINISHING

After the first riser form is removed, the face of the riser should be plastered, using the concrete wearing-surface mix. An outside edger is used to round the corner of the tread, and an inside edger is used to finish the corner at the bottom of the riser. A wood float should be used to provide a gritty, safe, non-skid surface on the treads.

Concrete steps should be cured in the same manner as walks are cured.

Riser forms are removed, starting with the top riser.

Face of the riser is plastered with concrete.

An outside edger rounds the corner of the tread.

Wood floating the treads assures a gritty, safe, non-skid surface.

Colored Finishes for Slabs

Many pleasing decorative effects can be achieved by the use of colored concrete in and around homes for patios, floors, stepping stones, walks, driveways, swimming pool decks, etc. There are four methods of producing colored concrete finishes: (1) the one-course method, (2) the two-course method, (3) the dry-shake method, and (4) stains, dyes, or paints. The first three methods give the most satisfactory results.

Dyes, stains, or paints are normally used only when it is necessary to color an existing slab. It is difficult to obtain a uniform color with dyes or stains; thus, the manufacturer's directions should be very closely followed. Paints, especially where subject to heavy traffic, wear away soon and must be continually renewed if a good appearance is to be maintained.

The one-course method consists of adding the appropriate amount of color pigment to the concrete in the mixer, producing a uniform color throughout the entire slab. The pigment must be a pure mineral oxide especially prepared for use in concrete. Both synthetic and natural pigments are satisfactory if they are insoluble in water, free from soluble salts and acids, fast to sunlight, fast to alkali and weak acids, have only limited amounts of calcium sulfate, and are ground fine enough so that 90 per cent passes a 325-mesh screen. The amount of pigment used should be the minimum amount necessary to produce the desired color, but never more than 10 per cent by weight of the cement. Full-strength pigments will normally produce a good color when 7 lb. are mixed with 1 bag of cement; 1½ lb. per bag normally produces a pleasing pastel color. White portland cement will produce cleaner, brighter colors and should be used in preference to normal grey portland cement, except for black or dark grey colors. To maintain a uniform color throughout the slab, proportioning of all materials in the mix must be carefully controlled by weight. Mixing time should be longer than normal to assure uniformity. To prevent streaking, the dry cement and color compound should be thoroughly blended before adding to the mix.

The two-course method consists of placing the base course in the usual manner, allowing it to stiffen and the surface water to disappear, and then placing the top ½ to 1 in. of colored concrete. This method is frequently used because of the economies offered. The savings in materials normally more than offset the slightly higher labor cost.

The dry-shake method consists of applying a dry color material that may be purchased from various manufacturers ready for use. Its basic ingredients are mineral oxide pigment, white portland cement, and specially graded silica sand or fine aggregate. Do not select, proportion, and mix a dry-shake material on the job.

After the concrete has been screeded and darbied, and free water and excess moisture have evaporated from the surface, the surface should be floated by either power or hand float. If by hand, a magnesium or aluminum float should be used. Preliminary floating should be done before the dry-shake material is applied—to bring up enough moisture for combining with the dry material. Floating also removes any ridges or depressions that might cause variations in color intensity. Immediately after the floating operation, the dry material is shaken evenly by hand over the surface. If too much color is applied in one spot, nonuniformity in color and possibly surface peeling will result.

The first application of the colored dry-shake material should use about two-thirds of the total amount needed (in pounds per square foot as specified). In a few minutes this dry material will absorb some moisture from the plastic concrete; it should then be thoroughly floated into the surface, preferably by a power float. Immediately, the balance of the dry-shake material should be distributed evenly over the surface. This should also be thoroughly floated and made part of the surface, taking care that a uniform color is obtained.

All tooled edges and joints should be "run" before and after the applications.

Shortly after the final floating operation, the surface should be power-troweled. If work is being done by hand, troweling should immediately follow the final floating. After the first troweling, whether by power or by hand, there should be a lapse of time—the length depending upon such factors as temperature, humidity, etc.—to allow the concrete to increase its set. Then the concrete may be troweled a second time to improve the texture and produce a denser, harder surface.

For exterior surfaces a second troweling is usually sufficient. Then a fine, soft-bristle push broom may be drawn over the surface to produce a roughened texture for better traction under foot. Smooth surfaces are slippery and hazardous when wet.

For interior surfaces a third hard troweling could be specified. This final troweling should be done by hand to eliminate any washboard or trowel marks. This final hand troweling produces a smooth, dense, hard-wearing surface.

Colored slabs, as with other types of freshly placed concrete, must be cured thoroughly.

After thorough curing and surface-drying, interior surfaces may be given at least two coats of special concrete floor wax containing the same mineral oxide pigment used in the dry-shake material. This wax is also available from various reliable manufacturers. Care should be taken to avoid any staining, such as by dirt or foot traffic, during the curing and drying period and before waxing.

APPENDIX C

APPENDIX C

Finishing Concrete Surfaces–

TEXTURED FINISHES FOR SLABS

Fig. 1. Medium brush texture.

Fig. 2. Heavy wavy brush texture.

Fig. 3. Swirled float finish.

Fig. 4. Patterned float finish.

Variation in texture of concrete surfaces is limited only by the imagination of the designer and the skill of the craftsman. Many interesting and practical textured finishes can, in fact, be produced with less effort and expense than a smooth-troweled surface.

Finish texture can be varied as desired, from a smooth, slick, polished appearance to the roughness of a frozen gravel path. The smoothest finish is produced by a highly skilled workman and a steel trowel, with the final troweling taking place when the surface is very hard.

A light brushing with a soft hair brush will slightly reduce the gloss of such a finish.

Progressively heavier brushing of progressively softer concrete produces increasingly rougher finishes. Brushing newly floated concrete with a fiber broom produces a rugged surface for use where mud, moisture, or heavy traffic makes the added safety of a nonskid texture a necessity (Fig. 1).

Patterns of Texture

Patterns of texture lend visual interest as well as surer footing. Methods of obtaining such patterns include drawing a brush across the surface in wavy lines (Fig. 2), brushing in alternate directions, or combinations of these.

Other texture variations can be produced by floating the surface (Fig. 3). A smooth matte finish is attained by holding the steel trowel flat as a float and finishing with swirling motions. Medium textures are produced by aluminum or magnesium floats, and coarser textures by wood, cork, or carpet floats. Patterns are introduced by using the float in a series of uniform arcs or twists (Fig. 4).

Fig. 5. Travertine or keystone finish.

Fig. 6. Rock salt finish.

Travertine Texture

A travertine (or keystone) texture requires a more elaborate procedure. After the concrete slab has been struck off, darbied, and edged in the usual manner, the slab is broomed with a stiff-bristle broom to ensure bond when the finish (mortar coat) is applied.

The finish coat is made by mixing 1 bag of white portland cement and 2 cu.ft. of sand with about ¼ lb. of color pigment. Yellow is generally used to tint the mortar coat, but any mineral oxide color may be used. Care must be taken to keep the proportions exactly the same for all batches. Enough water should be added to make a soupy mixture having the consistency of thick paint.

This mortar is placed in pails and thrown vigorously on the slab with a dash brush to make an uneven surface with ridges and depressions. The ridges should be about ¼ to ½ in. high. The surface is allowed to harden enough to permit a cement mason on it with kneeboards.

The slab is then steel-troweled to flatten the ridges, leaving the slab surface smooth in some places and rough or coarse-grained in the low spots. Depending on the amount of mortar thrown on the slab and the extent of troweling on this mortar coat, many interesting texture variations can be produced (Fig. 5). The slab may then be scored into random geometric designs before curing.

A similar texture can be produced by scattering rock salt over the troweled surface and then pressing it into the concrete with a trowel. After the concrete has completely hardened, the salt is washed away by thorough flooding with water. The dissolved salt will leave pits or holes in the surface (Fig. 6).

Neither the keystone nor rock salt finishes should be used in an area subject to freezing weather. Water trapped in the recesses of these finishes tends, when frozen, to break up the surface.

Finishing Concrete Surfaces—

PATTERNED FINISHES FOR SLABS

Fig. 1. Wood "joint" forms for flagstone finish.

Fig. 2. Laying out flagstone pattern with wooden strips.

Fig. 3. Floating in wooden strips.

A wide variety of finishes can be used to enhance the beauty of any concrete slab. One increasingly popular method of embellishing sidewalks, driveways, and patio slabs is the use of incised patterns, including carved flagstone, geometric, or inlaid leaf designs.

Carved Flagstone Patterns

Random flagstone patterns make an attractive finish for patio, sidewalk, or poolside slabs. Such patterns are easily made by embedding prepared wooden "joints," which are removed after the slab has hardened. Wood lattice stock (¼x1½-in.) is cut into varying lengths of from 4 to 32 in. Individual pieces are finished by carving the sides into irregular jagged shapes. Edges must be undercut to ease removal and prevent locking of the wood into the slab surface (Fig. 1). Curling of the wood strips may be prevented by thoroughly soaking them in water prior to use or by waterproofing with two complete coats of good varnish.

After the slab has been screeded and darbied, it is allowed to set until ready for finishing—in this case somewhat sooner than normal. The wooden joints are laid out on the slab in the desired pattern (Fig. 2). Very small or complex shapes should be avoided.

As soon as the pattern is laid out, the wooden strips are pressed into the concrete and the surface is floated. The top of the wood should be just flush with the surface of the concrete (Fig. 3).

Fig. 4. Cleaning wooden strips.

Fig. 5. Removing joint forms.

Fig. 6. Filling joints with contrasting mortar.

The concrete may then be troweled for a normal gray color, or if desired, a different color can be added at this time.

To ensure uniformity of color, it is best to use a factory-prepared color topping. Color toppings consist of portland cement and fine aggregate in equal proportions, plus a pure mineral oxide pigment to produce the desired color. This pigment is an extremely fine powder and must be applied as a dry shake. Dry-shake color is thrown over the surface with a swinging arm motion. The powder is released between spread fingers; this breaks it up and produces a more uniform distribution. For best results, first spread out half the required amount, then float and trowel the surface before adding the second half.

After floating the second application, and before troweling, the top of the wood strips are cleaned of any paste that may have been carried over them. A patching trowel or putty knife can be used to scrape the wood clean (Fig. 4). A final steel-troweling will then bring the wood joints and concrete to a uniform surface, which can be left smooth or be lightly brushed.

The following day the curing cover can be taken off, and the wooden strips are removed by lifting with a patching trowel (Fig. 5). The slab may be left with depressed joints or with the joints filled in with a contrasting mortar. A natural gray slab with white mortar joints is very attractive; a colored slab looks good with natural gray joints.

Before filling the joints, the slab should be flooded with water to keep the slab cool and the joints damp. Immediately before troweling in the mortar, the

APPENDIX D

Note to Instructor:

Slides and original photos for the illustrations in APPENDIX D are available from the Portland Cement Association at either address:

680 Wilshire Place Los Angeles, Calif. 90005	or	235 Montgomery Street San Francisco, Calif. 94104

(a) Transmits the original FAA Form 337 to the owner/operator.

(b) Forwards the copy to the local FAA office within 48 hours.

(2) AIs should insure that the copy is an exact and legible reproduction of the original. The signatures should not be carbon copies but original signatures in ink.

(3) In the event the FAA Form 337 has been completed for spare parts or components, both copies of the form with the approval portion (item 7) completed should be attached to the part or component until it is installed on an aircraft.

(a) Those items identifying the component with a particular aircraft and the owner's name and address will be left blank on the form.

(b) The installing mechanic will complete both copies of the form by filling in the blank items and will sign for the installation in the aircraft records. He should make reference to the FAA Form 337 in his record entry.

(c) The original copy of the completed FAA Form 337 goes to the owner/operator of the aircraft upon which the component was installed.

(d) The duplicate copy is forwarded to the FAA office for the area where the installing mechanic is operating.

d. When FAA Form 337s are received the FAA office may review them for completeness and accuracy. In the event they find discrepancies, they will return the form to the approving AI and request that it be corrected. Since it usually entails considerable time and effort in locating the owner/operator's copy of the form to make corrections, the AI should review the form carefully at the time of approval. The most common causes for FAA return of the form are:

(1) Item 8 (reverse of the form) lacks sufficient information to adequately locate and describe the repair or alteration and the basis for approval. The information given in this block should be extremely specific in identifying the data that was utilized in making the repair or alteration. A general reference to FAR 43 or AC 43.13-1 for repairs is not sufficient. Identify specific drawings, sections in AC 43.13-1, or manufacturer's instructions. If an advisory circular is utilized, identify it by title, number, and issuance date.

CIIS 2114

high degree of smoothness as do high-speed highways, it is possible and desirable to use simple hand methods for finishing.

Another exception is coarse aggregate size. In general, the coarse aggregate should not be larger than ¼ the pavement thickness. In many cases 3/4-inch maximum size aggregate will be most economical and satisfactory.

SUBGRADE PREPARATION

The first step in the construction procedure is that of subgrade preparation. (Slide 2) One of the most important points to remember in relation to the subgrade is that of uniformity -- both uniformity in compaction and uniformity in moisture content. Uniform compaction will be obtained unless you have uniform moisture. Subgrades should be compacted at or slightly above optimum moisture contents.

For low traffic streets, no subbase is required, and the pavement will be constructed directly over the basement soil, referred to in this talk as "subgrade".

GRADING

(Slide 3) The first step in preparation of the subgrade begins with grading work. In established neighborhoods, this generally consists of removing old pavement and cutting to grade.

In new areas, grading is sometimes accomplished in two steps. (Slide 4) The first step is major grading to sidewalk elevation with pans and scrapers. (Slide 5) The second step is grading to just above the final subgrade elevation, with final grading deferred until after forms are set.

(Slide 6) Except in very hilly areas, most streets in residential areas will be built in cuts, primarily as a result of the need to drain adjacent properties. (Slide 7) Where fills are required, they should be constructed in accordance with recognized embankment practices.

If a subbase is to be used, it is constructed to grade prior to the setting of forms.

Colored Finishes for Slabs

Many pleasing decorative effects can be achieved by the use of colored concrete in and around homes for patios, floors, stepping stones, walks, driveways, swimming pool decks, etc. There are four methods of producing colored concrete finishes: (1) the one-course method, (2) the two-course method, (3) the dry-shake method, and (4) stains, dyes, or paints. The first three methods give the most satisfactory results.

Dyes, stains, or paints are normally used only when it is necessary to color an existing slab. It is difficult to obtain a uniform color with dyes or stains; thus, the manufacturer's directions should be very closely followed. Paints, especially where subject to heavy traffic, wear away soon and must be continually renewed if a good appearance is to be maintained.

The one-course method consists of adding the appropriate amount of color pigment to the concrete in the mixer, producing a uniform color throughout the entire slab. The pigment must be a pure mineral oxide especially prepared for use in concrete. Both synthetic and natural pigments are satisfactory if they are insoluble in water, free from soluble salts and acids, fast to sunlight, fast to alkali and weak acids, have only limited amounts of calcium sulfate, and are ground fine enough so that 90 per cent passes a 325-mesh screen. The amount of pigment used should be the minimum amount necessary to produce the desired color, but never more than 10 per cent by weight of the cement. Full-strength pigments will normally produce a good color when 7 lb. are mixed with 1 bag of cement; 1½ lb. per bag normally produces a pleasing pastel color. White portland cement will produce cleaner, brighter colors and should be used in preference to normal grey portland cement, except for black or dark grey colors. To maintain a uniform color throughout the slab, proportioning of all materials in the mix must be carefully controlled by weight. Mixing time should be longer than normal to assure uniformity. To prevent streaking, the dry cement and color compound should be thoroughly blended before adding to the mix.

The two-course method consists of placing the base course in the usual manner, allowing it to stiffen and the surface water to disappear, and then placing the top ½ to 1 in. of colored concrete. This method is frequently used because of the economies offered. The savings in materials normally more than offset the slightly higher labor cost.

The dry-shake method consists of applying a dry color material that may be purchased from various manufacturers ready for use. Its basic ingredients are mineral oxide pigment, white portland cement, and specially graded silica sand or fine aggregate. Do not select, proportion, and mix a dry-shake material on the job.

After the concrete has been screeded and darbied, and free water and excess moisture have evaporated from the surface, the surface should be floated by either power or hand float. If by hand, a magnesium or aluminum float should be used. Preliminary floating should be done before the dry-shake material is applied—to bring up enough moisture for combining with the dry material. Floating also removes any ridges or depressions that might cause variations in color intensity. Immediately after the floating operation, the dry material is shaken evenly by hand over the surface. If too much color is applied in one spot, nonuniformity in color and possibly surface peeling will result.

The first application of the colored dry-shake material should use about two-thirds of the total amount needed (in pounds per square foot as specified). In a few minutes this dry material will absorb some moisture from the plastic concrete; it should then be thoroughly floated into the surface, preferably by a power float. Immediately, the balance of the dry-shake material should be distributed evenly over the surface. This should also be thoroughly floated and made part of the surface, taking care that a uniform color is obtained.

All tooled edges and joints should be "run" before and after the applications.

Shortly after the final floating operation, the surface should be power-troweled. If work is being done

by hand, troweling should immediately follow the final floating. After the first troweling, whether by power or by hand, there should be a lapse of time—the length depending upon such factors as temperature, humidity, etc.—to allow the concrete to increase its set. Then the concrete may be troweled a second time to improve the texture and produce a denser, harder surface.

For exterior surfaces a second troweling is usually sufficient. Then a fine, soft-bristle push broom may be drawn over the surface to produce a roughened texture for better traction under foot. Smooth surfaces are slippery and hazardous when wet.

For interior surfaces a third hard troweling could be specified. This final troweling should be done by hand to eliminate any washboard or trowel marks. This final hand troweling produces a smooth, dense, hard-wearing surface.

Colored slabs, as with other types of freshly placed concrete, must be cured thoroughly.

After thorough curing and surface-drying, interior surfaces may be given at least two coats of special concrete floor wax containing the same mineral oxide pigment used in the dry-shake material. This wax is also available from various reliable manufacturers. Care should be taken to avoid any staining, such as by dirt or foot traffic, during the curing and drying period and before waxing.

FORMS

(Slide 8) At present, most street pavements are built with forms. The use of formless pavers for this purpose may not be too far in the future. One equipment manufacturer is right now working on a slipform machine to pave street, curbs and sidewalks in a single pass.

Forms are normally set following subgrade compaction. (Slide 9) They may be either of wood or steel construction. When the finishing work will be done with light equipment, wood forms are quite satisfactory.

(Slide 10) Forms should be carefully set to the required line and grade to ensure both a smooth riding surface and proper drainage of surface water. This slide shows how well wood forms can be set.

(Slide 11) Forms should be well anchored and supported so that they will not move under the pressure of concrete and finishing operations. This slide shows a Symons steel pin nailed with double-headed nails to a wood form.

(Slide 12) The usual procedure for setting forms involves setting blue tops for grade reference, followed by a string set to line and grade from the blue-tops. From this stringline, forms are set to grade. Grade stakes are normally set 1½ to 2 feet outside of the form line.

FINE GRADING

(Slide 13) The next operation following form setting is that of fine grading. This is accomplished by planing the subgrade, which has been intentionally left slightly on the high side so that the planer is always cutting -- not filling low spots.

(Slide 14) This may be done by the use of a motor patrol grader. (Slide 15) or it may be done with an inexpensive subgrade planer riding on the forms.

(Slide 16) Following planing, the subgrade needs to be recompacted. Here you see a tandem roller, commonly used for

this purpose.

(Slide 17) This is a simple wood scratch template which is pulled along the forms to check the final grade and to ensure correct pavement thickness. Pavement thickness is as important to the contractor as it is to the inspector.

PLACING

(Slide 18) The final grade check is followed by placing and finishing of the concrete. Since most of the concrete used in street work will be ready-mix, the following comments will be based on placement from ready-mix trucks.

(Slide 19) It may be desirable to operate the ready-mix trucks between the forms. However, if trucks cause rutting or displacement of the subgrade, it may be necessary to use lighter trucks, provide suitable runways, or deposit concrete from outside the forms. Just prior to placing concrete, it is usually necessary to dampen the subgrade to prevent absorption of mix water from the concrete. This can be easily accomplished using water from the tank on the truck mixer.

There are many techniques used for striking off, consolidating and finishing, all of which when used properly can produce an excellent pavement. (Slide 20) The first step is to place the concrete on the subgrade. It should be spread as uniformly as possible, USING THE CHUTE OF THE TRUCK AND NOT BRUTE STRENGTH AND SHOVELS.

(Slide 21) The use of a vibrator will prevent honeycomb along the forms and keyways.

After spreading, the concrete must be consolidated and struck off level with the forms. Any one of the following items of equipment may be used to accomplish this, varying from the more sophisticated down to the simplest:

1. Iowa Curbmaster. (Slide 22) This piece of equipment extrudes the desired shape of curb as it is driven electrically along the forms. (Slide 23) The curb form is set full height when this type of equipment is used.

(The following devices require the outside form to be set in two operations. The first form is set to pavement thickness, the following item of equipment used, and a second form is tacked on for subsequent construction of the curb)

2. Clary Roller. (Slide 24) This consists of three driven rollers, two which turn one direction, and the other counter-rotates.

3. Thor Vibrator. (Slide 25) This has a series of vibrating steel bands along the bottom.

4. Vibrating beam. (Slide 26) A very common device used for construction of floors.

5. Oscillating screed. (Slide 27) This motor-driven device "see-saws" two boards back and forth across the concrete.

6. Pipe roller. (Slide 28) Perhaps one of the simplest, but a very effective piece of equipment. It has been used to build very smooth slabs 36 feet wide and there is no reason other than weight why it cannot be used for slabs up to 50 feet wide.

There are many other devices, using various ways of doing the job, too numerous to mention here.

FINISHING

(Slide 29) After the concrete has been spread, struck off, and consolidated, it is floated, if necessary, to close any holes in the surface and to remove any marks left by the previous operations. The float should be at least 4 feet wide and should not be used in such a manner as to create bumps in the pavement. The improper use of this tool is one of the most frequent causes of rough pavement.

Following floating, the pavement is straight-edged with a 10-foot scraping straightedge to remove any irregularities in the surface. (Slide 30) This item of equipment, too often overlooked, can be the major factor in providing a good

riding pavement. Frequently, it may be used in place of the float shown in the previous slide, or in combination with it. After strike-off and consolidation, the least amount of hand-work that can be done in order to get a satisfactory surface is most desirable. Excessive working brings water and fines to the surface (very pronounced when air-entrained concrete is not used).

CURBS

(Slide 31) Next follows the construction of the integral curb. Integral curb construction is recommended for all pavements requiring curbs, for two obvious reasons. One reason is the economy realized in the construction operation. Integral curbs built with the pavement in a one-step operation provide savings not possible with separate curb and gutter construction. Further, the time saved is most significant, since the entire lane including curbs, base and surface is built in a single pass and can be opened to traffic in seven days. In addition, integral curbs substantially strengthen the pavement edges, thereby reducing stresses and deflections and increasing the structural capacity.

There are several methods of forming integral curbs and they may be formed to almost any desired cross-section.

Enough concrete to construct the curb may be left along the form line, or extruded as shown here with the Curb-master, (Slide 32) or, (Slide 33) Forms for the curb can be tacked on later and enough concrete deposited with which to construct the curb. (Slide 34) This must be done while the previously placed concrete is still plastic and as quickly as possible.

The curb is then shaped to the desired cross-section using templates similar to the one shown here. (Slide 35) Templates can be made to match any ordinary curb shape.

(Slide 36) These are inserted in the concrete left for construction of the curb, one end resting on the pavement and the other on the top of the curb form.

(Slide 37) Workmen shape the curb according to the template using a straightedge, as shown here.

Since curbs and gutters are a part of the drainage system, it is important that they will drain properly to the nearest water outlet. (Slide 38) Grade can be checked with a string line, as shown.

FINAL TEXTURING

(Slide 39) Finally, the pavement is edged and is ready for final texturing. Just after the water sheen leaves the surface is about the proper time for texturing. Texturing before or after this may result in less than the desired gritty surface. (Slide 40)

(Slide 41) For best skid resistance, the use of a burlap drag at the proper time is recommended. (Slide 42) This should include the curbs to provide a uniform appearance. (Slide 43) Some engineers prefer the appearance of a broomed finish.

CURING

(Slide 44) A most important, and frequently ignored, part of any concrete work is the need for proper curing. If the concrete surface is allowed to dry out after finishing without any effort made to retain mix water, crazing, plastic shrinkage cracks, and lack of strength may be the likely result. This applies to all concrete work.

The function of curing is to prevent rapid drying of the concrete during the hardening period. This can be accomplished in several ways: Through the use of wet burlap, (Slide 45) waterproof paper, (Slide 46) polyethylene, or by the use of liquid membrane-forming compounds. (Slide 47) This latter method is one of the best methods. It is probably the easiest and cheapest methods. White compounds are recommended for two reasons: One; the inspector and contractor can be sure of adequate coverage, and two; the white surface will reflect heat, reducing the internal heat of the concrete, and therefore,

(2) Omission of, or incorrect reference to, model and serial number. Transfer this information directly from the nameplate or registration form of the aircraft concerned. Do not use manufacturers' trade names.

(3) Signatures missing, either mechanic or AI.

(4) The FAA Form 337 was completed for a minor repair or alteration or solely for a weight and balance report. Weight and balance reports, in most cases, are separate documents and usually incorporate lists and loading schedules.

e. Weight and Balance. Weight and balance entries are no longer required on the FAA Form 337. As this data is no longer reviewed by FAA inspectors, it is imperative that weight and balance checks and computations be made very carefully. Since practically every aircraft manufacturer uses a different method of weight and balance control, it would be impossible to provide a universally adaptable method. The examples provided in Figure 12, will be general in nature and can be modified or revised as needed to fit the aircraft involved. When revising weight and balance data, these general rules should be followed:

(1) The weight and balance data should be kept together in the aircraft records.

(2) When making revisions, use a permanent easily identified method, with full-size sheets of paper large enough to contain complete computations and to minimize the possibilities of their becoming detached or lost.

(3) The pages should be identified with the aircraft by make, model, serial number, and registration number.

(4) The pages should be signed and dated by the person making the revision.

(5) Describe nature of the weight change.

(6) The old weight and balance data should be marked superseded and dated.

(7) The new page should show the date of the old figures it supersedes.

(8) Appropriate fore and/or aft extreme loading conditions should be investigated and the computations shown.

its degree and speed of shrinkage, particularly important when joints are to be sawed.

JOINTS

(Slide 48) Joints seem to be somewhat of a mystery. They shouldn't be. Concrete, like any other rock-like material, adjusts itself to changes of temperature and moisture by cracking into small enough units as to limit stresses. This will normally result in slabs with dimensions of 15 to 20 feet out-of-doors. (Slide 49) Jointing does not eliminate cracking, rather it weakens the slab so as to force it to crack in a neat straight line rather than in an unsightly random pattern.

(Slide 50) Joints may be installed in plastic concrete by impressing as you see here. Much care and skill is needed to avoid creating a bump.

(Slide 51) Or, they may be sawed into the concrete shortly after it has gained some strength and hardness. Sawing eliminates the possibility of creating the bumps sometimes caused by hand-finishing methods. However, time of sawing is critical, and it must be done as soon as the concrete will accept the saw without excessive raveling of the joint. Any delay beyond this will see the formation of nature's "joints" occur before the man-made joints. After a crack has already occured, no further sawing should be done at that location. Transverse joints are normally spaced about 15 feet apart, and longitudinal joints about 12 feet. Reinforcement with mesh and dowels is not necessary.

(Slide 52) It is often desirable to box-out around manholes and catch-basins, returning at a later date to place concrete around the castings. (Slide 53) A good arrangement is to orient the box-out so that the corners coincide with both longitudinal and transverse joints.

CONCLUSION

(Slide 54) In answer to my question at the beginning as to how much equipment is needed to pave a concrete street, $500 will provide every basic item. This will include the following tools:

A CAREER
in traffic engineering

21425

FOREWORD

This booklet is for young men and women in high school and for those entering college who are facing a key decision in life: choice of a career. It is intended primarily for persons interested in science and engineering, especially those who desire an understanding of traffic engineering and of the opportunities it offers as a profession.

The traffic engineer deals with the dynamics of the transportation system. His use of electronics, his concern with drivers and pedestrians, and the swiftly changing nature of his work all serve to make his a challenging and rewarding profession.

A 1963 survey found a shortage of over 1400 traffic engineers in the United States alone, additional to the 7000 then employed. The shortage is becoming greater. Increasing traffic problems here and in other countries make it abundantly evident that the need for traffic engineers will grow.

Traffic growth has long outpaced the building and widening of streets and highways. This situation seems likely to continue. Keeping ever-growing traffic moving with maximum safety and efficiency while helping to plan and bring into being needed highway improvements are the major tasks of traffic engineering.

The Institute of Traffic Engineers acknowledges with appreciation the assistance of the Automotive Safety Foundation in preparing both the earlier edition and this booklet. Financial support of publication by the Foundation and ITE Participating Organizations is also much appreciated.

The text of this edition was prepared primarily by an ITE Technical Council committee composed of Henry K. Evans (Chairman), Martin J. Bouman, George A. Hill and Adolph D. May, Jr.

FIG. 2—Lincoln Tunnel, New Jersey Toll Plaza

INTRODUCTION

At one time, there were only two kinds of professional engineers: *military engineers* who built and operated the buildings, structures and machines of the armed forces of those days; and *civil engineers* who applied their knowledge of materials, of laws of physics and energy, and of mathematics to all the other needs of civilization. This, in fact, is how the name "civil engineer" started.

As man learned more about the world around him and how to mold its resources to his needs, it became impossible for any one person to command all its accumulated knowledge. Specialized branches of engineering began to emerge. This process continues today and will tomorrow, as engineers proceed toward their goal of learning and applying knowledge to better our way of life.

Traffic engineering is one such specialized limb on the civil engineering branch of the tree of engineering. Its roots are in the common knowledge of mathematics and science. Its strength is in the trunk of engineering methods and discipline. Among the group of civil engineering limbs are traffic engineering, municipal engineering and highway engineering. The pages to follow will tell you more.

21427

HISTORY

Traffic engineering in a broad sense is the use of engineering principles and methods to help create or bring about safe, orderly and efficient highway transportation. It makes use of systems analysis and operations research. Although the profession is modern, it has precedents as old as vehicles on wheels. One-way streets, a familiar traffic engineering tool today, were used in ancient Rome. Five hundred years ago the Incas planned and built a "controlled access" highway in Peru which bypassed cities and villages. Traffic counts were made in London in the 1840's as an aid to street planning.

Modern traffic engineering, however, owes its impetus to the automobile, which brought great changes in our way of living. Many roads and streets which served the horse and wagon era well, proved unsuitable for large volumes of fast-moving motor vehicular traffic.

The rapid popularity of this new way of travel brought many things–not all of them good. The numbers of persons killed and injured in the use of the "horseless carriage" rose to alarming totals, and major urban streets often became jammed with vehicles.

FIG. 3–Traffic congestion in 1910. Dearborn & Randolph Streets, Chicago.

21428

In the early nineteen twenties, the first "traffic engineer" joined the highway engineer, planner and others seeking safe and efficient highway transportation. Planning, use-designing and managing safe, convenient trafficways for urban living offer a challenge to the best brain-power which traffic engineers can bring to this team.

Now the traffic engineer is a part of every state highway department in the United States and of most large city and metropolitan county governments. His job continues to grow in importance as highway transportation needs increase in magnitude and complexity. He has a part in planning, designing and operating the 41,000 mile National System of Interstate and Defense Highways–the biggest public works project ever undertaken. The traffic engineer, with traffic police, is responsible for the traffic management and operation of the system as more sections are opened for travel. He also participates in development of electronic equipment and other means to make freeway use safer and easier.

"Electronic drivers" may someday be as important on the highway as "automatic pilots" are in air transportation. When and if this comes about, the traffic engineer will have taken an active part in the development and will be the official in charge of operating such traffic guidance devices.

Every year the United States increases in population equal to another Chicago. Every year a million acres of "new city" are created. These people and this land must be served by streets and other travel facilities planned to provide the greatest transportation advantages while preserving the

FIG. 4–If future cars are like this, how will traffic engineering be affected?

FIG. 5–Automatically guided "Urb-mobile", – a possible vehicle of the future.

21429

amenities of the city as a place to live and the efficiency of the city as a place to work. The traffic engineer is making important contributions in meeting this tremendous challenge: in analyzing the transportation values of alternative plans for major street systems, in establishing functional designs, and in supervising traffic operation over these systems when completed. Urban redevelopment, off-street parking, rapid transit systems, new shopping centers and airport expansions are creating additional demands for traffic engineers.

THE TRAFFIC ENGINEERING PROFESSION

The Institute of Traffic Engineers is the professional society of traffic engineers. Many also belong to the American Society of Civil Engineers, National Society of Professional Engineers, and other professional organizations. The statistics shown in Table I are from a survey of the United States membership of the Institute of Traffic Engineers. In August 1968, the Institute had over 3400 members.

The Institute of Traffic Engineers defines traffic engineering as "that phase of engineering which deals with the planning, geometric design and traffic operations of roads, streets and highways, their networks, terminals,

abutting lands and relationships with other modes of transportation for the achievement of safe, efficient and convenient movement of persons and goods." There are opportunities for many different applications of this field of knowledge as shown by Tables I and II.

EMPLOYMENT AND EDUCATION

Most traffic engineers are employed by government—city, state or federal—or by engineering consultants. Table 1 shows that Federal agencies employ modest numbers, but large cities and state highway departments employ about half of the practicing traffic engineers in the Institute. One of five Institute members is in consulting work and the use of such consultants is growing. Substantial numbers are engaged in teaching and research.

97% of all practicing traffic engineers have college degrees in engineering and a majority are registered Professional Engineers, proving their engineering knowledge by passing special examinations given by most states. Almost half of the practicing members of the Institute have taken university graduate training.

Qualified women hold responsible positions in varied activities of this profession.

ACTIVITIES

Table II presents another "average" picture of traffic engineering. It shows the relative time spent by the more advanced traffic engineers on specific activities. Those in charge of traffic engineering activities usually work in an organization with other people and often supervise the work of numerous other engineers and technicians. Report writing is an important ingredient of all activities shown in Table II. These aspects should be borne in mind in deciding what subjects to study in becoming a traffic engineer.

FIG. 6—Rapid transit uses median of Eisenhower Expressway in Chicago.

21431

FIG. 9

DUTIES OF THE TRAFFIC ENGINEER

The amazing growth of highway travel has created a great backlog of highway improvement needs. Thus, while the traffic engineer must constantly seek to improve efficiency of operations of today's over-crowded streets and highways, he is at the same time engaged in helping to engineer a tremendous program of new roads.

Some such activities require the use or study of: problem-solving techniques, higher mathematics, statistical methods, computer processing of data, human factors including capabilities and behavior of drivers and pedestrians, light, sound and physics; as well as design, economics and other subjects fundamental to highway engineering.

As the traffic engineer develops and gains experience, his authority and scope of work will usually increase. He may become the head of a major department as has happened in many governmental and private organizations. He will assume many administrative duties on such traffic-related matters as public transportation, parking, terminals, street construction and maintenance, and urban planning.

The traffic engineer's responsibilities and opportunities are many and varied. They cannot be completely described in a few words or a few pages. Nevertheless, the following pages will introduce four typical traffic engineers and will help you to understand kinds of work of traffic engineers.

Mr. A– City Traffic Engineer. He heads the Department of Traffic and Transportation in his city. On his desk in the morning is a report of a problem discovered the previous night in the traffic signal system

21433

LOCATION

Traffic engineers are at work in most large urban communities throughout the world. As people in less advanced parts of the world obtain and use motor vehicles more, the need for trained traffic engineers increases. For example, besides the federal and state governments and most cities of 50,000 to 100,000 population or more in the United States, official traffic engineering positions have been created by many cities, regions and nations in over 60 other countries.

FIG. 7—Pedestrian overcrossings are one means of physically separating pedestrian and vehicular traffic, an increasingly necessary measure.

FIG. 8—If you select Traffic Engineering as a career, one of your responsibilities will be to assure that pedestrians reach their destinations safely and quickly, and to reduce conflicts between pedestrians and vehicles.

21432

Mr. C has responsibilities in highway planning, geometric design, construction and operations which affect the lives of all citizens of the state. He spent his morning with the highway design engineer going over the plans for a new highway. The designer is, to an extent, a traffic engineer too. The needs and abilities of the highway user are also in his mind. But he must consider all the physical parts of the highway as well to be sure that the road will be smooth, strong, easily maintained and a good investment of public funds. Therefore, he relies on State Traffic Engineer C to point out features which might confuse or endanger the driver; to advise him as to whether traffic signs can be effectively located if certain proposed road design features are used; and to tell him just where curbs and traffic islands should be placed at important intersections requiring channelization and traffic signals.

THE TRAFFIC ENGINEER PLAYS AN IMPORTANT PART IN STREET AND HIGHWAY TRANSPORTATION - FROM BEGINNING TO END BOTH IN RESEARCH AND APPLICATION

FIG. 16

Following this conference, Mr. C went with one of the assistant traffic engineers to inspect a rural cross road shown by accident records to be particularly dangerous. Traffic counts and studies plus the pattern of accidents had indicated that traffic control signals might have to be installed. The assistant engineer's detailed study, however, had brought to light other factors. Instead of signalization, which would require many cars to stop, he recommended widening the pavement for a few hundred feet and painting new lines so that left-turning cars could pull out of the lane of

FIG. 17
Accident investigation.

21437

SEEKING EMPLOYMENT

Opportunities in the traffic engineering profession are increasing rapidly. For years there have been more positions than qualified candidates to fill them. A shortage of 1400 highway transportation engineers was disclosed by an ITE survey in 1964. All indications – including expanding highway programs, population and travel growth, rapid development of urban areas – are that the deficiency of trained traffic engineers will grow for some years to come. Qualified job applicants are hence in the fortunate position that they can often select not only the type of employment but also the general location in which they wish to work.

Usually the young engineer enters the traffic engineering field through government employment although engineering consultants are offering increasing opportunities, some including experience in other countries. U.S. Civil Service Regional Offices and their local "boards" maintain a file of position offerings in their own and other locales. Notices in "Traffic Engineering" magazine and other engineering-oriented publications supply information on job opportunities. Also the Executive Director of the Institute of Traffic Engineers will be happy to recommend one or more names of practicing traffic engineers in your geographical area who may be willing to discuss traffic engineering and your interests and qualifications with you.

FIG. 36–Peak hour traffic at places having a large number of employees, often requires special study.

FIG. 37–If Shopping Center parking entrances and exits are designed properly, congestion on the access roads can be avoided.

fast through vehicles. This, plus the removal of some trees too close to the intersection (obstructing drivers' view) and an improvement in the illumination, was decided on as a far better solution. Later a recheck showed that the improvements did increase safety without sacrificing efficiency.

On the way home, Mr. C's thoughts turned to another problem --- the forthcoming hearings before the State Highway Commission on a proposed new freeway, which had excited much citizen interest, both pro and con. Mr. C would be called on to present the State's findings relative to improved traffic service for the State-supported route. He decided that as long as he was going to a college town for the hearings, he would arrange to confer with his friend, Professor D of State College.

FIG. 18—Controlled crash tests with anthropometric dummies, belted and unbelted, help greatly in guiding many decisions.

Professor D teaches Highway and Traffic Engineering at State College, and he is typical of many traffic engineers whose work is teaching and research. While most are on faculties of colleges and universities, some work for the federal government or national organizations; others work in industry, developing better traffic control and research methods and devices. In common with Professor D, they are all looking for answers to the many important problems yet unsolved in this field.

On the morning Mr. C's letter arrived concerning a conference, the professor was working with his advanced students on the safety values of belt restraining devices. Experimental vehicles equipped with carefully made anthropometric dummies in driver and passenger seats were being crashed against abutments and different types of guard rails to find out how best to protect the occupants from injury with seat belts of different designs and with variations in the interior design of the vehicle.

21428

FIG. 20—Testing of driver tension.

FIG. 21—Road surface smoothness testing.

More county governments are establishing traffic engineering agencies as the continuing trend toward concentration of people in metropolitan areas results in a "spilling out" beyond municipal boundaries and produces increasing traffic problems to such urbanizing areas on the fringes of cities. The day-to-day duties of the typical county traffic engineer have many elements in common with those of both the city and state traffic engineer. The county traffic engineer must also often diplomatically arrange for cooperation among municipalities within the county.

The federal government and other agencies are employing increasing numbers of traffic engineers in planning and research. Increasing federal programs of financial aid in highway development, traffic research and urban area planning have increased the need for federal leadership in techniques and standards.

FIG. 22—Motion pictures made of high congestion and accident locations are sometimes used to determine the type of improvement needed.

APPENDIX 1. PUBLICATIONS

1. REGULATIONS.* The following list includes regulations the AI uses most frequently. Those marked with an asterisk should be available for reference when taking the test for Inspection Authorization.

PART NO.	FEDERAL AVIATION REGULATIONS (NEW) TITLE	PRICE
*65	CERTIFICATION: AIRMEN OTHER THAN FLIGHT CREWMEMBERS	.35
*43	MAINTENANCE, PREVENTIVE MAINTENANCE REBUILDING, AND ALTERATION	.55
* 1	DEFINITIONS AND ABBREVIATIONS	.45
*21	CERTIFICATION PROCEDURES FOR PRODUCTS AND PARTS	.60
*23	AIRWORTHINESS STANDARDS: NORMAL, UTILITY, AND ACROBATIC CATEGORY AIRPLANES	1.25
27	AIRWORTHINESS STANDARDS: NORMAL, CATEGORY ROTORCRAFT	.70
33	AIRWORTHINESS STANDARDS: AIRCRAFT ENGINES	.40
35	AIRWORTHINESS STANDARDS: PROPELLERS	.30
37	TECHNICAL STANDARD ORDER AUTHORIZATIONS	1.00
*39	AIRWORTHINESS DIRECTIVES VOLUME 1, UNDER 12,500 LBS. VOLUME 2, OVER 12,500 LBS.	.20 5.25 6.00
45	IDENTIFICATION AND REGISTRATION MARKING	.20
47	AIRCRAFT REGISTRATION	.25
*91	GENERAL OPERATING AND FLIGHT RULES	1.25

* See Important Notice, Appendix 2, page 1.

FIG. 23—Motion picture camera being used to study vehicle passing characteristics.

FIG. 24—Traffic and safety features of new road are checked during construction stage.

Many large metropolitan areas in the United States have established continuing transportation study agencies, employing traffic engineers and planners, in accordance with the Federal Highway Act of 1962 which requires such continuing study work.

FEDERAL LEGISLATION

The Highway Safety Act of 1966 and federal administrative provisions which call for considerable emphasis on traffic operational measures in urban areas, indicate increasing interest in the kinds of programs for which traffic engineers are responsible. These federal developments will greatly expand present traffic engineering programs, and will open doors to new applications for traffic engineering skills.

FIG. 25—Scale model shows how proposed highway improvements have been adapted to the community and to proposed developments

Snow emergencies and accidents can create traffic and detour problems.

FIG. 26 FIG. 27

REWARDS - PERSONAL AND PROFESSIONAL

The rewards for any work well done are measured in personal satisfaction and warranted recognition. One of the strong appeals of traffic engineering is knowledge of the many ways in which this work contributes to saving lives and reducing the human costs of traffic accidents. The traffic engineer also sees day-to-day evidence of results of his work in improved traffic flow and living conditions.

If you are one who wants to be "where the action is", consider who is responsible for making the instant decisions changing the flow of traffic when a snow storm makes some streets impassable, or when a major highway accident or other emergency requires traffic to be rerouted. When

FIG. 28—Many unusual traffic problems can arise to keep a traffic engineer busy.

police, fire equipment and ambulances are necessary at a large conflagration, who directs them as to emergency routings, changes in traffic plans and operations? Usually the traffic engineer makes these decisions and takes these steps, or his advice to others results in these emergency actions.

Traffic engineering offers financial and other rewards in abundance. Almost immediately the young traffic engineer will find that he is given tasks which call for individual judgment, and which well done, provide a sense of accomplishment and service to his fellow men. At first, of course, he will have assistance and supervision by more experienced engineers. But, as he proves himself, he will be given more responsibility and later will supervise other engineers and technicians.

FIG. 29—Traffic engineers and other municipal officials discuss traffic problems of mutual interest at a regional workshop.

FIG. 30—Traffic engineers discuss needed traffic improvements.

He will be in contact frequently with traffic committees and boards as well as the public, and his recommendations and actions will be publicized often in newspapers and on radio and TV.

The U.S. Bureau of Public Roads and several state highway departments offer in-service training programs wherein the young engineer gains experience in a variety of jobs: design, construction, traffic studies, computer programming, material testing, etc. At the end of the training program, he selects the field of greatest interest to him. Cities and states often help their employees obtain graduate training in traffic engineering.

21443

controlling downtown traffic. The electronic computer which adjusts the signal timing to meet traffic changes did not perform well after the big show at the auditorium. Though the computer works fast and accurately, it cannot think for the engineer.

The auditorium situation was a special one requiring additional facts and study. Mr. A assigned the task of obtaining the needed data to his traffic survey engineer. He then left his office to attend a meeting of the City Planning Commission. An urban renewal project for the out-of-date wholesale district would require changes in the street pattern. His transportation planning staff had studied the kinds and numbers of vehicles these streets would be serving, and the traffic effects of proposed street pattern changes. One of his long-range studies, made 2 years before, had anticipated this very development.

At lunch, Engineer A was the speaker at a downtown businessmen's meeting. He told the group about current problems frequently referred to him involving requests for such things as changed curb parking regulations, more off-street parking and installation of traffic signals. Looking toward the future, he also told of plans underway aimed at establishing a freeway surveillance system to monitor traffic on the new city freeway, regulate its use and vary the speed limits in accordance with traffic and weather conditions. Mr. A described how the use of closed-circuit TV cameras for visual monitoring and vehicle detectors on the freeway operating in conjunction with an electronic computer, would greatly increase safety and facility of freeway operation.

During the afternoon, Mr. A studied and approved the report of his traffic operations engineer on an improved arrangement of signs and pavement markings to protect children at school crossings. Lieutenant Jones, head of the Traffic Division of the Police Department, had pointed out the need for these new standards from reports of his patrolmen.

FIG. 10—Technician modifying signal timing.

FIG. 11—Sign messages need to be concise, yet easily understood.

21434

FIG. 12—Traffic surveillance control center, John C. Lodge Freeway, Detroit.

The last assignment that day was an appointment with Mr. B, Consulting Traffic Engineer. Mr. B's firm was hired to locate and provide functional design for a new freeway to be built in the city, mainly with state and federal funds. To assure that there would be enough lanes and ramps at the right places, he needed traffic counts and other data from Mr. A. These figures would be adjusted to account for growth and changes in traffic patterns which would take place in years to come.

This was one of several projects Mr. B was supervising. His firm provides expert traffic engineering service to cities, highway departments and private organizations in several states and occasionally to foreign countries. Mr. B naturally moves around quite a bit. On the previous day he had been in a nearby city advising a shopping center owner on how best to design for all the pedestrian, service, truck, and private car traffic his center would attract.

FIG. 13—Lane control signals on John C. Lodge Freeway.

21435

FIG. 14—Traffic survey to obtain information on drivers' origins and destinations.

FIG. 15—Motorist being interviewed in O.D. Study.

The next day at his office, Mr. B inspected the first results of a traffic origin-destination survey just completed. In this study, motorists on several roads were interviewed as to their trips: where they started, where they were going, and how often they travelled that route. The purpose of this study, which Engineer B had planned and supervised, was to find out whether a proposed toll bridge would carry enough traffic to be economically sound, and if so, which of several possible locations would be best.

Before he finishes this study, Mr. B, Traffic Consultant, will need a lot of help. Bridge engineers will study the locations he selects and make preliminary bridge design decisions to permit reasonably correct estimates of the costs of buying needed land at each location and of building the bridge. Assistance of planners and economists will be required in predicting future land use and economic development, as well as computer programmers and data analysts to aid in projecting and assigning future traffic. Mr. B will put all this information together in reaching his final recommendations.

Near the end of the day, Mr. B telephoned a professional friend, Mr. C, State Traffic Engineer. Mr. C is in charge of the Division of Traffic and Planning in the State Highway Department. Since this state is large, he has Traffic Engineers as assistants in different parts of the state to help supervise traffic operation on several thousand miles of state highways.

21436

After lunch, Professor D has time for his favorite project. He knows that water flows through a pipe according to definite laws of physics. An apple falls from a tree according to the law of gravity. In card games, predictions can be made by the statistical laws of chance. Professor D is trying to improve on the "modal splits" equation used to estimate how many people will utilize public transit vs. private autos in planned future metropolitan transportation systems. People make choices and act based on many factors and considerations. All of the values of statistics and higher mathematics available to Professor D including the University's giant electronic computer, have not produced a fully satisfactory mathematical model yet; but he is not discouraged. Already the things that he has learned in trying to develop a more perfect "law of traffic flow" have helped Messrs. A, B and C in their work as professional traffic engineers.

FIG. 19—Computerized traffic control system in San Jose, Cal.

RESEARCH

Research is an important part of the work of consultants and specialists in federal agencies as well as of many other traffic engineers who, in addition to their regular duties, search for new knowledge to do their jobs better.

21439

The young traffic engineer can be assured of adequate financial rewards similar to other engineering and professional positions and higher than most non-engineering pursuits. The increasing shortage of engineering personnel has caused a healthy rise in starting salaries so that most engineering college graduates are earning more than most of their contemporaries. The steady increase in the traffic engineer's earning ability as he gains experience (see graph below) will be very satisfying.

As in other professions, individual ability counts most and outstanding individuals find great opportunities in traffic engineering for increases in responsibility, service and income. The figures in the graph below may be useful for comparison purposes. However, they should be considered thoughtfully. For example, as engineering salaries are rising, the 1967 figures in this chart will soon be outdated. Moreover, no attempt has been made in this chart to evaluate "fringe" benefits such as retirement plans and other privileges, which are often substantial.

FIG. 31—Table of Salary Graphs

LEARNING TO BECOME A TRAFFIC ENGINEER

A person who has finished school without traffic engineering training can often "learn on the job" by obtaining employment where he will be assigned to work under a traffic engineer. Or if he has a college degree in engineering or science, he can seek admission to a graduate program in traffic engineering. In-service training courses, given for short periods by agencies such as the Institute of Traffic Engineers, employers and educational institutions, can be helpful and deserve consideration, especially if college level training cannot be obtained. However, the best preparation for becoming a traffic engineer is to obtain the proper education in high school and college.

HIGH SCHOOL The foundation for traffic engineering begins in high school. Almost all traffic engineers are college graduates and your high school advisor can tell you how a student must prepare in high school to meet the entrance requirements of engineering colleges. You can take further beneficial steps in preparing for traffic engineering by studying civics and government and by improving your ability to speak and write well. These skills are important, as well as skills in engineering and science.

FIG. 32—Careful planning has provided an attractive promenade and play area while meeting vehicular traffic needs effectively.

FIG. 33—It might well become one of your jobs "Prospective Traffic Engineer", to plan the main stream routings for sports spectators.

Farm Machinery Safety for Vocational Agriculture Instruction. (Teaching Units).

Indiana State Office of the State Superintendent of Public Instruction, Indianapolis.
MF AVAILABLE IN VT-ERIC SET.
Vocational Instructional Materials Laboratory, School of Technology, Indiana State University, Terre Haute, Indiana 47809.
PUB DATE - Mar70 98p.

DESCRIPTORS - *AGRICULTURAL EDUCATION; *VOCATIONAL AGRICULTURE; *AGRICULTURAL MACHINERY; *AGRICULTURAL SAFETY; *TEACHING GUIDES; AGRICULTURAL ENGINEERING; SAFETY EDUCATION; SECONDARY GRADES; BIBLIOGRAPHIC CITATIONS; FILMS

ABSTRACT - Intended for vocaticnal agriculture teachers in teaching farm machinery safety for secondary grades, this teaching unit was developed by the Indiana State Office of Public Instruction. The unit includes 21 lessons which should take from 25 to 35 hours for instruction. Each lesson includes teaching suggestions, objectives, motivation techniques, and questions for discussion and tests. References and film listings are appended. (GB)

2. TECHNICAL DATA. The following should be available when taking the AI test:

a. Aircraft Type Certificate Data Sheets and Specifications. Basic subscription consists of specifications and type certification data sheets in all weight groups; monthly supplements for approximately one year; the Aircraft Listing; and Index. Prices: $20.00 domestic; $25.00 foreign. Order from Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.

b. Aircraft Engine and Propeller Type Certificate Data Sheets and Specifications. Basic subscription consists of engine and propeller specifications; monthly supplements for approximately one year; the Listings; and Indexes. Prices: $16.00 domestic; $20.00 foreign. Order from GPO.

c. The Airworthiness Directives are now summarized in two volumes, one covering small aircraft and the other large aircraft. Each volume may be purchased separately on subscription which consists of the basic volume plus annual supplements.

(1) Summary of Airworthiness Directives for Small Aircraft. Volume I, $5.25 domestic; $6.50 foreign. Order from GPO.

(2) Summary of Airworthiness Directives for Large Aircraft. Volume II, $6.00 domestic; $7.25 foreign. Order from GPO.

d. Acceptable Methods, Techniques, and Practices. These advisory circulars replace the policy material formerly contained in CAM 18. Order from GPO.

(1) AC 43.13-1, Acceptable Methods, Techniques, and Practices - Aircraft Inspection and Repair, $3.00 domestic; $4.00 foreign.

(2) AC 43.13-2, Acceptable Methods, Techniques, and Practices - Aircraft Alterations, $2.00 domestic; $2.50 foreign.

3. ORDERING FARs AND TECHNICAL DATA. Orders for the FARs and technical data should include remittance by check or money order made payable to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Except where otherwise designated, orders from foreign countries should include an additional amount of about one-fourth the purchase price to cover foreign postage. Remittance should be by International Money Order or by a draft on a U.S. bank.

21446

COLLEGE If your career goal is traffic engineering, your choice of college is important. First, you should select one with a strong engineering program and one which offers undergraduate courses in the highway and traffic field. Your high school advisor, the engineering faculty of many colleges and universities, and the Institute of Traffic Engineers can help you with this choice. There are many fine schools offering such instruction, including the following:

Notes: Letter g denotes graduate courses only. The list may be incomplete, particularly for schools outside the U.S. or schools with a recently added transportation curriculum. Almost all of the U.S. colleges and universities listed have a member of the Institute of Traffic Engineers on their faculty. For many colleges and universities outside the United States, the same is true and the number for which it is true is growing.

FARM MACHINERY SAFETY
...Tractor

(R)

I. Teaching Unit I . . . Importance of Tractor Safety

II. Suggestions for Teaching:

A. Show film, "Farm Tractor Safety - A Family Affair."

B. Have students make a local survey of tractor accidents in the past year.

C. Collect additional data on tractor accidents - local, state and national.

D. Save newspaper and magazine articles on tractor accidents.

E. Have reaction time demonstrations - See Farm Safety Memo S-49, Pg. 2.

III. Objective:

To develop the students' awareness of the importance of tractor safety.

IV. Motivation:

A. Show the film, "Farm Tractor Safety - A Family Affair."

B. Accidents kill more young people than all diseases.

C. Accidents never just happen, they are caused.

D. Do reaction time demonstration, see memo S-49.

E. According to the 1966 Indiana Farm Accident Report, from 1956 1964, 386 people were killed in accidents involving farm tractors. There were about 14,000 tractor accidents during this time in Indiana and over 33% of them involved persons under twenty years of age.

F. Discuss local data collected.

G. Here are some famous last words:

- It can't happen to me.

- I can get by this time.

- I've got a special way.

- I don't have time for safety.

FIG. 35—Many Universities offer a curriculum in Traffic or Transportation Engineering.

Engineering curricula which offer elective courses in such subjects as transportation planning, geometric design and traffic characteristics will not leave much time for other elective subjects. However, courses in statistics, psychology, law, public administration, engineering report writing, public speaking and personnel management, will all be helpful in the practice of traffic engineering.

GRADUATE STUDY Many traffic engineers continue their formal education beyond college graduation. This is not necessarily done immediately upon graduation, as often a few years of practical experience make such graduate study more meaningful. Approximately 40 percent of traffic engineering graduate students have been supported with fellowships; an equal number have had other kinds of financial support such as teaching assistantships or employer support. The Institute of Traffic Engineers will gladly furnish you with information as to available fellowships.

The opportunity for graduate traffic engineering study is now available at a number of colleges or universities. Your own Alma Mater, your employer, or the Institute of Traffic Engineers can assist you in making your selection. Many of the schools previously listed offer graduate traffic engineering courses.

SOURCES OF INFORMATION

The Institute of Traffic Engineers is one of a number of organizations interested in the traffic engineering profession. The organizations and publications listed hereinafter can provide you with further information and answer your questions about the field.

FIG. 38.– Typical Traffic Engineering Studies & Reports

FOREWORD

The Federal Literature uses the terms Farm Tractor Safety and Machinery Safety. These terms are also used most of the time in this publication. However, to simplify the title we have used the term FARM MACHINERY SAFETY to include both tractor and other machinery. FARM MACHINERY SAFETY is also used as the title for each unit with the word "Tractor" added when appropriate.

Reference is made to the publication "A Suggested Program Guide for Implementing the 1968 HAZARDOUS OCCUPATIONS ORDER in Agriculture." This was distributed to all Indiana teachers of Vocational Agriculture in 1968 and additional copies are available from the State office. The list of "16 hazardous areas of agricultural employment" on pages 1 and 2 were modified in 1969.

INTRODUCTION

The following is a brief summary of the Federal regulations concerning 14 and 15 year olds working in hazardous occupation areas. For details, see the latest edition of "A Suggested Program Guide for Implementing the Hazardous Occupation Order in Agriculture" or "Federal Register", Volume 34, Title 29 - Labor, Chapter XIII - Bureau of Labor Standards, Department of Labor, Part 1500, Sub-part E-1, for more detailed information.

For both the tractor (20 horsepower and over) and other farm machinery specified as hazardous, the employer shall instruct the 14 and 15 year olds on safe and proper operation of the specific equipment the student is to use. The student shall be closely supervised and his safety checked at least three times each day (midmorning, noon, and midafternoon). The student shall satisfy whichever of the following requirements are appropriate.

Vocational Agriculture Training Exemption

(1) Operating a TRACTOR over 20 horsepower

- (i) 14 years old and older
- (ii) child is familiar with normal working hazards in agriculture
- (iii) has completed at least 15 hours training program as specified by department of HEW
- (iv) has passed written and practical test
- (v) employer has a copy of certificate signed by parent and vo-ag instructor

(2) Reference to hazardous FARM MACHINERY as specified in the latest edition.

- (i) has completed the tractor program (1)
- (ii) has completed 10 hours of additional training on farm machinery safety
- (iii) has passed written and practical test on safe machinery operation
- (iv) employer has copy of certificate signed by parent and vo-ag instructor

Only when a student (14 and 15 years old) has completed the above requirements can he work for an employer in a hazardous occupation area. Even after completing the training program, he still CANNOT work in certain areas. (See "Hazardous Occupations Order" for detailed listings of these items). Be sure this reference is current because these work areas will be reclassified from time to time.

The vocational agriculture teacher and the parent both must sign the exemption certificate before the student is exempt from the hazardous occupations law. The teacher is not responsible in case of an accident. His signature certifies that the student has satisfactorily completed the safety training program set up by the Federal agencies.

COMMENTS ON TRACTOR SAFETY TEACHING UNITS

The tractor safety program must have a minimum of fifteen (15) hours of instruction. Twenty-five (25) hours are considered more desirable. The emphasis on the program is safety and quality of instruction.

Teaching units marked (R) are required. Other units are optional. The tractor units must be completed prior to the units on machinery.

The student must pass a written and practical test prior to receiving certification for tractor operation.

COMMENTS ON MACHINERY SAFETY TEACHING UNITS

The Machinery Safety Program must have a minimum of ten (10) hours of additional instruction. Units marked (R) are required. Depending upon the time lapse between the two major units (tractor and machinery), portions of the tractor units may have to be repeated to supplement or reinforce the machinery units.

The student must pass a written and practical test prior to receiving a machinery operation certificate.

COMMENTS

These teaching units are not intended to be complete. They should be supplemented with information that pertains to your area of the state. All equipment should be discussed in greater detail and safety precautions that pertain to a particular piece of machinery should be pointed out. These units are only a guide.

At the end of the tractor safety units and the machinery safety units, you will find sample questions. They are divided into groups that correspond with the teaching units. After teaching a major unit (tractor or machinery safety), a fifty (50) point written test must be given. If the student does not receive seventy percent (70%) or more, he cannot receive an exemption certificate. He is allowed to take only one retest in a given calendar year. In addition to the written test, the student must also take a practical test such as the one outlined at the end of each major unit. Use the attached score sheet to evaluate the student performance. Note all automatic disqualifications listed.

V. Central Problem:

Why is tractor safety important?

VI. Sub-Questions:

A. What is an accident?

1. The National Safety Council recommends that a reportable accident be defined as one that requires professional medical care or loss of one-half day or more of normal activity. (Such activities might include work, play, school, etc.)

B. What are the costs involved in an accident?

1. Damage to property.

2. Medical expense (Doctor's bill, hospital, medicine, undertaker?)

3. Time lost.

4. Increased insurance cost.

5. Hired labor to do your job.

6. Hidden costs.

a) Was the hay rained on?

b) Will the cows be milked properly?

c) Will the weeds over take your crops?

d) Will your injury slow you down in the future?

e) Will you have to sell the farm?

f) Will you ever be able to work again?

C. How many of you have been involved in a tractor accident or <u>near</u> accident?

D. What are some types of tractor accidents?

1. Tipping

a) Side

b) Back

2. Jack-knifing.

3. Automobile - tractor

5. PTO

6. Run over

7. Crushed between tractor and other object

E. What are some causes of accidents?

1. Failure to observe safety rules.

a) May not know the rules.

1) Haven't bothered to study the operator's manual.

2) Have never had safety instructions.

3) Have copied the wrong practices.

b) Fail to respect power and speed of moving machinery.

c) Tend to develop fearless attitude.

1) Haven't seen accidents happen.

d) See only the immediate problem.

1) You don't really gain if you have an accident while trying to get a little more work done.

2. Over 80% of all accidents are due to carelessness.

3. Being a safe operator is a matter of thinking about and avoiding hazardous situations.

4. It takes an accident 1/2 second to happen, a person with quick reactions might have a reaction time much slower, the operator may freeze or make the wrong move.

5. Daydreaming, thinking about Saturday night, etc.

VII. Evaluation:

A. Does the student understand the importance of tractor safety?

B. See Questions on Unit I (Tractor).

Due to the nature of the requirements regarding the testing of this unit, no sample questions will be given for each lesson. However, the questions referring to each lesson will be identified.

4. ADVISORY CIRCULARS. To receive advisory circulars, write to Department of Transportation, Federal Aviation Administration, Distribution Unit, TAD-484.3, Washington, D.C. 20590. You may ask to be put on the mailing list to receive those circulars that are free concerning subjects of interest to you such as:

AC 00 General
AC 10 Procedural
AC 20 Aircraft (Includes 30 and 40)
AC 60 Airmen
AC 70 Airspace
AC 90 General Operations
AC 120 Air Carrier and Commercial Operators

The basic number of an advisory circular is always the same as the FAR to which it is related. For instance, this handbook concerns FAR 65.95 and is so numbered.

a. General Aviation Inspection Aids. Advisory Circular 20-7 consists of a summary and 11 monthly supplements. Order from GPO: $2.00 domestic; $2.50 foreign for each subscription.

b. Summary of Supplemental Type Certificates. Advisory Circular 21-5 announces the availability of this summary. Order copies from the United States Government Printing Office and remit $9.00 (add $3.50 for foreign mailing) for each volume requested. Identify the publication as Summary of Supplemental Type Certificates, Advisory Circular, 21-5.

2. Substitute films available at the same address are:

a) "Tractor Tragedies"

b) "Farm Tractor Safety"

FARM MACHINERY SAFETY
...Tractor

I. Teaching Unit II . . . Pre-operating Procedures

II. Suggestions for Teaching:

A. Show film strip, "Tractor Operation and Daily Care"

B. Obtain operator's manuals for different models and makes of tractors.

C. Obtain a set of 4-H Tractor Program Books.

D. Make a poster, transparency or hand-outs of pre-operating procedures for tractors.

E. Collect broken and worn tractor parts.

III. Objective:

To make the students aware of the values of pre-operating procedure.

IV. Motivation:

A. Explain the value of preventative maintenance. Repairs that result from the lack of preventative maintenance are much more costly in time and money.

B. Show film strip, "Tractor Operation and Daily Care."

V. Central Problem:

Why be concerned with pre-operating procedures?

VI. Sub-Problem:

A. Why check crankcase oil level?

1. The crankcase oil should be checked daily. It is checked by the aid of a dip-stick or a plug level check. See your operator's manual for the specific location of the oil checking devices on your tractor.

2. The crankcase oil lubricates, cleans, cushions, and cools the engine parts. The oil must be clean and found in adequate amounts to do its job properly. See your operator's manual for more information on lubricants for your tractor.

7. Keep all controls free of foreign materials. This will reduce accidental moves.

8. Think and practice safety at all times.

VII. Evaluation:

A. Does the student understand all the pre-operating procedures and know why they are important?

B. See questions for Unit II (Tractor).

VIII. References:

A. Operator Manuals

B. Hazardous Occupations in Agriculture for 4-H Members, Pg. 23-25

C. 4-H Tractor Program Book 1, Pg. 55-58

D. Film strip. "Tractor Operation and Daily Care" or "Tractor Maintenance."

E. Hazardous Occupations Order in Agriculture, Pg. 8

a) An engine low on oil will over-heat and wear excessively. Both cause delays, costly break-downs, and loss of power.

b) An engine with water in its oil can cause rusting and extensive wear to an engine.

c) An engine with fuel in its oil can cause damage similar to water in the oil. It also creates a fire hazard due to static electricity.

d) Anti-freeze in the crankcase oil can also cause serious damage to the engine. The heat of the engine will cause the anti-freeze to form deposits on the parts of the engine, these deposits will then burn leaving a harmful residue.

B. Why check the cooling system?

1. The cooling system controls the temperature of the engine.

a) A thermostat opens and allows more water to flow through the radiator when the engine is hot.

b) If the engine is cold, the thermostat closes thus decreasing the amount of water that flows through the radiator.

NOTE: If an engine operates too cold or too hot, it will consume more fuel and a power loss will be noticed.

2. Checking the cooling system:

a) Most modern tractors have a pressurized cooling system. It should be checked daily.

b) Never attempt to remove a radiator cap while the coolant is boiling or hot.

c) When removing the radiator cap to check the coolant level, observe the following rules:

1) Place a rag over the radiator cap. This prevents burning of hands on the hot metal.

2) Allow the pressure to escape by pressing a special button found on some caps or by loosening the cap part way. Be careful of steam burns.

3) After all the pressure has escaped, remove the cap slowly keeping your body away from the filler hole.

E. Why service the air cleaner?

1. Every gallon of fuel burned in an engine requires from 6,000 to 9,000 gallons of air. If the air is not cleaned the engine can be completely ruined in one day.

2. See your operator's manual for specific information on servicing your air cleaner.

3. Some general rules in servicing the air cleaner are:

   a) Never service the air cleaner while the engine is running. The engine will pull dirt into the cylinders while the cleaner is off.

   b) Service the air cleaner at least every 10 operating hours.

   c) Oil-bath air breathers must have clean oil every time they are serviced. Be sure to remove all dirt from the cup before adding new oil.

   d) The dry filter must be changed according to manufacturer's specifications. Compressed air can be used to remove excess surface dirt from the filter.

   e) The pre-cleaner collecting bowl should always be kept free of dirt.

   f) The pre-cleaner filter should be cleaned daily. It can be blown out with compressed air and some models can be cleaned out by washing them in a clean solvent. Never use gasoline.

F. What should one remember about clothing and miscellaneous items?

1. Clothing should not fit too loose nor too tight. It should be loose enough to allow freedom of movement but tight enough to prevent being caught in moving parts. Gloves, loose pant legs and loose sleeves are especially dangerous.

2. Keep mud, dirt, oil and tools off the mounting step. This will help to reduce falls.

3. Check the steering for excess play and loose bolts.

4. Do not jump from the tractor. Use hand hold and mounting steps.

5. Check the wiring and ignition systems for possible shorts or worn insulation.

6. Keep flame away from the battery. The battery gives off an explosive gas when it is being charged.

B. What are the principles and affects of rear wheel spacing?

1. The wider the rear wheels are spaced the more stable the tractor will be.

2. Be certain that the tractor is securely jacked when moving the rear wheels in or out. Only jack up one side of the tractor at a time. Never get under a tractor while it is jacked up. Rear wheels on some tractors can be moved in and out without jacking up the tractor.

C. What are the principles and affects of front wheel spacing?

1. In general it is probably a good practice to keep front wheel spacing wide. Don't let this give you too much confidence because wide front-ends are not rigid. The tractor can tilt many degrees before it touches the axle.

2. Be certain that the front of the tractor is jacked securely before adjusting the front wheels.

3. When operating a tricycle type tractor in mud or snow, the front wheels should be spaced as wide as possible by reversing the dish of the wheels. This prevents mud and snow from being packed around the wheels and bearings.

D. What are the principles and affects of adding weights?

1. There should always be a balance between the weight on the front and rear of the tractor. If a heavy rear mounted implement is placed on the tractor, weight should be added to the front, for counter balance. Likewise many front-end loader accidents could be eliminated by adding rear weights.

2. See your operator's manual for specific information about the addition of weights on your tractor. Only add weights when it is necessary.

3. If you add weights only to the rear you increase your chances of tipping backward.

4. Excessive weight on the front end may reduce rear wheel traction and result in side tipping.

E. What are the principles, placements and uses of controls?

1. The controls on your tractor make it possible for you to control the movements of the tractor. The safe operator will know the function and location of all controls of the tractor he is operating.

2. The starting control, on most late model tractors, is a key. This control completes a circuit between the starting motor and the battery. Some tractors have a safety device that requires the transmission to be in neutral before the starter will engage.

3. The tractor has at least one clutch, it controls the transmission. Some tractors have auxiliary clutches that control the PTO or other secondary power supplies. All clutches should be disengaged before starting or dismounting from the tractor. Consult your operator's manual for specifics concerning clutches on your tractors.

4. The throttle controls the engine speed of your tractor. It is actually a device that adjusts the spring pressure of the governor on a gas tractor. A diesel throttle simply controls the amount of fuel being injected into the cylinders.

5. The brakes should be adjusted evenly. The brakes have three primary functions: to assist in making sharp turns, to make stops, and to keep the tractor from rolling while traveling at high speeds the brakes should be locked together. This helps to prevent upsets due to unexpected turns.

6. The steering controls the turning movements of your tractor. It should be checked regularly to be certain it is safe and does not have excessive play.

7. The transmission is a device that transfers the engine power into a driving power. It has many speeds and the operator must be familiar with the locations of all possible selections. Some tractors have automatic transmissions.

8. There are other controls than will be covered in greater detail in later lessons. They are hydraulic controls, three-point hitches, etc.

VII. Evaluation:

A. Does the student know how to make proper adjustments to meet operational needs.

B. See questions on Unit III (Tractor).

VIII. References:

A. 4-H Tractor Program, Book 1, Unit 5, Pg. 37-38.

B. 4-H Tractor Program Leader's Manual and Demonstration Guide, Pg. 10.

C. Purdue Leaflet S-48, Pg. 1-2.

D. Hazardous Occupations in Agriculture for 4-H Members, Pg. 17-18, 36.

d) Never add hot water to a cold engine or cold water to a hot engine.

e) Keep the cooling system clean. Remove any foreign material from the radiator fins and flush the cooling system annually to prevent the accumulation of rust deposits.

C. Why check the lubricant level?

1. Lubrication is used to clean, cushion and cool moving parts, not only in the engine but also in the drive train and other power transfer points.

2. Your operator's manual will tell you the proper oil level and recommendations for servicing these lubrication points. The manual will also tell you the type and weight of oil to use.

3. When checking the lubricant levels be sure that no dirt falls into the libricant.

4. Be sure to clean all grease fittings before attempting to lubricate.

D. Why keep water and sediments from fuels?

1. A tractor will not run properly if it does not receive the proper amount and quality of fuel. Water or sediments will prevent the proper fuel from reaching the engine.

2. Fuel should be stored in a manner to prevent water or sediments from entering the tractor's fuel tank.

3. The sediment bowl and fuel filters are designed to prevent water and sediments from reaching the engine. These devices must be serviced regularly so that they will operate properly.

a) Be careful when changing or servicing the sediment bowl or fuel filter. If fuel is spilled on a hot engine a fire could result. Check for leaks, immediately after replacing any fuel line parts.

4. If sediment reaches the carburetor, it can cause permanent damage.

5. Foreign materials in the cylinder can also cause extensive damage.

FARM MACHINERY SAFETY
...Tractor

I. Teaching Unit IV . . . Starting and Stopping the Tractor Engine

NOTE: This is not meant to include movement of the tractor.

II. Suggestions for Teaching:

A. Have several different tractors and explain how to start and stop each one.

B. Have a student tell how to start and stop his tractor's engine. Then have some other student to try and start and stop another tractor following the directions of the first. Point out the differences.

III. Objective:

To teach the student how to properly start and stop different types of tractor engines.

IV. Motivation:

A. Have a student tell how to start and stop his tractor's engine. Then have some other student to try and start and stop another tractor following the directions of the first. Point out the differences.

B. Have some students start and stop tractor engines then point out errors.

V. Central Problem:

What is the correct procedure for starting and stopping a tractor engine?

VI. Sub-Problem:

A. Why should one never start a tractor engine inside a closed building?

1. A colorless, orderless gas, called carbon monoxide (CO), is given off by a tractor's engine. The gas can kill a person.

2. Sparks may come out of the exhaust system; creating a fire hazard.

IMPORTANT NOTICE

The Federal Aviation Administration is reissuing the Federal Aviation Regulations (FAR) in a volume system to be sold on a subscription basis by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402.

The purchase of a FAR volume will establish your subscription service with the Superintendent of Documents for automatic receipt of changes to the volume as issued by FAA.

The volume structure is:

Volume	FAR Part
I	1.
II	11, 13, 15, 21, 37, 39, 45, 47, 49, 183, 185, 187, 189.
III	23, 25.
IV	27, 29, 31, 33, 35.
V	43, 145, 149.
VI	91, 93, 99, 101, 103, 105.
VII	121, 123, 127, 129.
VIII	133, 135, 137.
IX	61, 63, 65, 67, 141, 143, 147.
X	151, 153, 155, 159, 165, 167.
XI	71, 73, 75, 77, 95, 97, 157, 169, 171.

As each volume is issued, an availability notification providing price and order form will be issued and distributed by the Superintendent of Documents, However, until all FAR Parts are grouped in their respective volumes and the volumes are available for sale from the Superintendent of Documents, the present system of obtaining individual FAR Parts and revision service to them will remain in effect.

B. What are the normal starting procedures?

1. Turn the fuel supply valve on. The fuel supply should always be shut off when the tractor is not in use. This practice will eliminate the possibility of explosion due to fuel vapors from a leaking fuel supply.

2. Be sure the seat is properly adjusted.

3. Be sure the transmission is in neutral or park and the brake is depressed. This will prevent the tractor from moving unexpectedly when it is started. Many modern tractors have safety features to prevent accidents of this kind.

4. Advance the throttle slightly.

5. Turn on the key and see that all gauges or indicator lights are working properly. Check your operator's manual for more detailed instructions.

6. Activate the starter and never crank the engine over 15 seconds at a time. If the engine does not start after 4 or 5 attempts try to find the trouble. Most operator's manuals have a trouble shooting section. Continuous cranking can deplete your battery and force fuel into the crankcase, creating a hazardous situation.

7. After starting allow the engine to warm up slowly before putting the engine under a heavy load.

C. How are the throttle and choke used?

1. The throttle is used to control the engine speed by regulating the spring tension of the governor.

2. The choke is used to enrich the fuel-air mixture when starting an engine by decreasing the air supply.

D. What is the proper way to crank or tow an engine to start it?

1. A hand crank is seldom found on the modern farm; however, when cranking an engine by hand, never put your thumb on one side of the crank and your fingers on the other. Keep your body out of the area where the crank rotates. If the engine were to backfire, the crank could break your thumb, your ribs, or an arm.

2. Before attempting to tow a tractor to start it, consult your operator's manual. Some tractors require special adjustments before towing.

3. If towing is attempted be sure that someone is on the tractor at all times and never tow at high rates of speed. Also, never tow for long periods or fuel will be forced into the crankcase. The person riding the towed tractor should be ready when the engine starts so that he will not ram the vehicle towing him.

4. A high percentage of backward tipping occurs while towing another vehicle. Be sure to hitch at or below the drawbar height and avoid having the rear wheels of the towing tractor lower than the front wheels.

5. Before starting to tow a tractor there should be some pre-arranged signals for stop and start.

E. What is the proper way to use the clutch and the brakes?

1. The clutch should always be engaged slowly, never pop the clutch. Keep all obstructions away from the clutch pedal and be certain that the clutch is fully engaged or fully disengaged. Never over-grease the throw-out bearing because it will allow grease to get on the clutch plate, causing it to slip.

2. Never ride the brakes. Apply them slowly. Keep the brakes evenly adjusted and lock them together when traveling at high speeds. Keep obstructions away from the brake pedals. If your tractor has power brakes, remember that it takes only a small amount of pressure to activate them.

F. How should one start a warm or cold engine?

1. Choking or use of starting fluid may be needed to start a cold engine. Starting fluid is extremely flamable so keep away from fire and sparks. Always allow the engine to warm up before operating.

2. A hot engine should never be choked. If the fuel mixture is too rich fuel may run out onto the hot engine causing a fire hazard or an engine backfire.

G. What are the shut-off procedures?

1. Disengage all clutches, reduce the engine speed and set the brakes before shutting off the engine. If the engine speed is not reduced the engine could backfire causing valves to warp or cause a fire. The transmission should be placed in park or in a low gear and the ignition key removed after the engine has been shut off.

VII. Evaluation:

A. Does the student know how to safely start and stop a tractor engine?

VIII. Peferences:

A. Your Tractor Operator's Manual.

B. Hazardous Occupation in Agriculture for 4-H Members, Pg. 29-30.

C. Hazardous Occupations Order in Agriculture, Pg. 9

FARM MACHINERY SAFETY
...Tractor

I. Teaching Unit V . . . Controlling Tractor Movement

II. Suggestions for Teaching:

A. Make up a situation with a tractor parked with many hazards around. Ask students to point them out.

B. Have one student move a tractor. Point out mistakes and overlooked hazards.

C. Duplicate the cartoon sheet found in the FFA tractor safety program kit and see how many hazards the students can find.

III. Objective:

To teach the student how to safely control the movements of a tractor.

IV. Motivation:

A. Refer to film showed in Lesson I and point out mistakes in controlling a tractor.

B. Have a student to move a tractor and point out mistakes he made or hazards he overlooked.

V. Central Problem:

What is the proper way to control the movements of a tractor?

VI. Sub-Problems:

A. How do tractor controls operate?

1. See your Operator's Manual.

2. Some controls are usually uniform.

a) Clutch

1) Left foot

2) Down - disengage

3) Up - engage

4) Hand clutches vary

b) Brakes

1) Brake nearest left wheel controls the left.

2) Brake nearest right wheel controls the right.

3) Brakes side by side and can be locked together.

4) Depress to apply brakes.

c) Steering

1) Get the feel of the steering wheel - power steering - turning radius.

2) Spinner knobs may catch on your clothing or hit wrist.

d) Others

1) See manual for location and directions for use.

B. Why keep area clear of obstructions?

1. You must be able to see; therefore, permit no riders or anything else that might obstruct your view.

C. What should one do before starting the move the tractor?

1. Double check all instrument readings.

2. Look around for possible hazards.

3. Place tractor in a low gear.

4. Release clutch slowly.

5. Increase throttle slowly.

6. Drive with special caution until you are completely familiar with the tractor and its surroundings.

D. Why reduce speed when approaching a turn?

1. When speed is doubled the possibility of an upset is four times as great.

2. Slow gradually for a turn, a slide or sudden stop may cause you to overturn.

3. Keep the center of gravity low to the ground to prevent tipping. For example, a raised loader creates a greater hazard than one lower to the ground.

4. All tractors should have a protective frame or crush-resistant cab and a seat belt to protect the operator in case of an upset.

5. Avoid sharp turns if possible, if not use extreme caution.

6. Jack-knifing is a serious problem while turning or stopping with a load behind a tractor.

E. What should one remember about using the clutch?

1. There are only two positions for a clutch, all the way in or all the way out.

   a) A partially engaged clutch will start slipping and will wear out quickly.

   b) When disengaging a clutch push it down quickly.

   c) When engaging a clutch, release it in a steady slow manner until it is fully released. Then keep your foot off it until you are ready to disengage it again.

2. Keep the clutch free of grease, mud and dirt so that your foot will not slip off.

3. Adjust the clutch at the first signs of slippage. Consult your manual for instructions.

4. If the clutch is difficult to reach, lengthen the pedal, if possible, or move the seat forward.

F. How should one shift gears?

1. The shifting of gears should be coordinated with the use of the clutch.

2. Never force the gear shift lever, you may damage the transmission.

3. Be sure the gears are engaged completely before releasing the clutch.

4. Be familiar with the shifting pattern.

5. Some tractors must be completely stopped before one can shift gears. On the other extreme some tractors have automatic transmissions.

G. What should one do before backing up?

1. Always look to see what is behind you before you start backing.

2. If you are backing a load that blocks part of your view, have someone to help guide you.

3. Always look back while backing, but remember the front of your tractor may hit something also.

4. Never back up at a fast rate of speed.

5. Be careful when turning while backing up because you might turn the steering wheel in the wrong direction or may turn to much.

6. Never back up any farther than absolutely necessary.

H. What is the proper way to stop?

1. Start preparing to stop far in advance and look for possible hazards.

2. Avoid sudden stops whenever possible.

   a) You can slide.

   b) The load may jack-knife.

   c) You may loose control and upset.

3. Reduce the throttle and apply both brakes easily. Do not take tractor out of gear until you have almost completely stopped.

4. After you have completely stopped -

   a) Set both brakes.

   b) Shut off tractor.

   c) Place transmission in low gear or park.

   d) If you are on a slope, block the wheels of the tractor and load.

5. If possible stop on level, solid ground.

6. Remove the ignition key to prevent an unauthorized person from moving the tractor.

VII. Evaluation:

A. Does the student
of a tractor?

B. See questions on

VIII. Reference:

As no one public
fore, no referen

understand how to safely control the movements

Unit V (Tractor).

ation discusses many of the above items; there-
ces are listed.

FARM MACHINERY SAFETY
...Tractor

I. Teaching Unit VI . . . Hitching to Tractor Operated Equipment

II. Suggestions for Teaching:

A. Refer to film in Lesson I

B. Use tractor training safety aid to demonstrate points (See Unit III).

C. Show film "Hitching and Belting Pointers."

D. Use examples of actual accidents in your community.

III. Objective:

To develop the ability to hitch the tractor to power driven equipment safely.

IV. Motivation:

A. Show "Hitching and Belting Pointers."

B. Ask students to tell about accidents or use examples you have collected.

C. Use model tractors and equipment to demonstrate.

V. Central Problem:

What is the proper method of hitching the tractor to tractor operated equipment?

VI. Sub-Questions:

A. What is the proper drawbar height?

1. When you hitch to a load, the load is trying to tip the tractor backward.

2. The higher the hitch, the greater the possibility of overturning the tractor.

3. Always keep the drawbar as low as possible, usually 13 to 17 inches above the ground.

Leadership in Curriculum Development; A Handbook for Teachers, School Administrators, and Consultants.

Glassboro State Coll., N.J. Curriculum Development Council for Southern New Jersey.
MF AVAILABLE IN VT-ERIC SET.
Curriculum Development Council for Southern New Jersey, No. 4 Gateway Hall, Glassboro State College, Glassboro, New Jersey 08028 ($1.50).
PUB DATE - 65 54p.

DESCRIPTORS - *VOCATIONAL EDUCATION; *CURRICULUM GUIDES; *CURRICULUM DEVELOPMENT; *LEADERSHIP RESPONSIBILITY; *TEACHER ROLE; CURRICULUM PLANNING; ADMINISTRATOR ROLE; CONSULTANTS; CHECKLISTS

ABSTRACT - Prepared by the Curriculum Development Council (CDC), this handbook was designed as a curriculum guide for administrators, teachers, and consultants. To help develop curriculum at the local level, the handbook states general principles for curriculum development and outlines specific processes and roles involved in curriculum change. Chapters are (1) Curriculum Development, (2) What Kind of Leadership, (3) Getting Started, (4) Maintaining Momentum, (5) The Roles to be Played, (6) Finishing the Job, and (7) The CDC in Operation. Also included are a leadership inventory, an orientation checklist, a checklist for consultants, and sources of reference materials. (JS)

VT 011 898

4. Always hitch to the **drawbar**. Never the seat, axle, or any other point even though just a little above the drawbar.

5. Raising the hitch to increase traction is a dangerous practice.

6. Never have a free swinging drawbar unless you are doing field work at a very slow speed.

B. How should one position a tractor during the hitching process?

1. Align the center of the drawbar with the center of the equipment hitch.

2. Get the drawbar as close as possible to the equipment hitch.

3. When the tractor is positioned, lock both brakes.

C. How should one attach equipment to the drawbar?

1. Always use a safety pin to hitch equipment.

2. Never get between the tractor and equipment while the tractor is in motion. This may seem unnecessary to the person who has been lucky in the past, but it only takes one time to kill or seriously injure.

3. Never try to lift heavy equipment--use a jack.

4. Move the drawbar or tractor if hitch does not align.

5. After the equipment is hitched to the tractor with a safety pin, remove any blocks that might have been used to prevent equipment from rolling.

D. What should one remember about hitching rear mounted equipment?

1. Be careful not to place too heavy a load on the rear of your tractor.

2. The weight of the rear mounted equipment should be added to the front of the tractor.

3. Be sure hydraulic system is full of oil.

4. Reduce speed while equipment is lifted.

5. Always use recommended locking pins--do not make your own.

E. What should one know about PTO standards and usage?

1. There are two types of PTOs.

a) 540 rpm - 6 tooth spline - standard

b) 1000 rpm - 21 tooth spline - more power - auxiliary

c) Never use adaptors to change from one type to another unless the speed of the PTO is changed accordingly.

F. How should one connect equipment with the PTO shaft?

1. Check equipment to see if it requires 540 rpm or 1000 rpm's to operate properly.

2. After you have the right type of PTO, align the teeth on the equipment's PTO shaft with the teeth on the tractor's PTO. On some equipment a hole for a lock pin in the PTO must also be aligned.

3. Slide shaft forward slowly until shaft is in the proper position. Now lock the shaft into position by releasing a spring loaded pin or by inserting a pin through the shaft and PTO stub.

G. What should one remember about safety shields for PTO shafts?

1. Always keep all PTO shields in place. A person can be completely wrapped around an unshielded PTO shaft in about one-half second.

2. Whenever you dismount the tractor, shut off the PTO.

3. Never get near a moving PTO even if the shield is in place.

4. Keep PTO shields in good repair.

5. Keep stubshafts shielded.

6. There are two types of PTO shields, the permanent shield (non-removable) and the inverted U shield.

H. What should one remember about connecting hydraulic cylinder hoses?

1. Never try to connect or disconnect hydraulic hoses if there is pressure on the line.

2. Be sure that all connections are tight.

C. What should one remember about the use of right away privileges?

1. Regardless of the fact that you have the right to use the highway, you are in a vulnerable position. So, far as your own safety and the safety of other highway users, stay off the main traveled portion of the highway whenever possible.

D. What should one know about turning at road speeds?

1. Don't -- Don't ever attempt to turn a tractor while traveling at road speed.

2. In turns tractors are easier to upset than nearly any other type of vehicle.

3. Slow to nearly a stop before attempting to turn, especially if you are pulling a load.

4. Allow extra room for trailing equipment when turning near bridges, posts, trees, etc.

E. What should one remember about slowing and stopping from road speeds with and without trailing equipment?

1. Never attempt to make sudden stops while traveling at high rates of speed. Plan ahead and anticipate slowing or stopping.

2. Most equipment being towed does not have brakes; therefore, the equipment will jack-knife if a sudden stop is attempted.

3. When towing equipment it takes longer to stop so allow for this.

4. Signal when you are planning to stop.

5. Loose gravel can cause an accident when stopping or turning at high speeds.

F. What about towing a farm tractor?

1. Before towing a farm tractor read the operator's manual. Some tractors require special treatment if they are towed.

2. Never tow at a high rate of speed. The tractor may upset. Also towing at a high rate of speed can over-heat wheel bearings or severely damage the transmission.

3. Display all safety warning devices while towing a tractor on a public highway.

G. What should one remember when entering and leaving main roads?

1. Be sure there are no cars coming for a long distance. If the car is travleing 60 mph and you pull out on the highway when the car is 1/16 (33 feet) of a mile away, the driver of the car has less than 4 seconds to bring his car under control. It will take the car at least 200 feet to make a full stop; therefore, if the driver doesn't see you for one second and if his reactions are not quick, he will hit you from the rear.

2. Signal all turns while on or leaving the highway. Be sure your signal is visible.

3. If you cannot signal due to equipment you are pulling, have someone following you signal.

4. Eliminate the use of blind corners of any other highway entrance when it is difficult to see or to be seen.

H. What local laws apply to farm tractors?

1. Indiana requires the SMV emblem on all vehicles traveling under 25 mph.

2. For night travel, Indiana requires red or amber flashing light that is visible at least 500 feet to the rear.

3. Indiana requires that you pull off to the side of the road and allow cars to pass if you are obstructing traffic.

4. License plates are required on farm tractors if they are being used on public highways for any other use than moving equipment from farm to farm. The same is true for farm-trailers and wagons.

VII. Evaluation:

A. Does the student know how to operate the farm tractor safely on the highway?

B. See questions on Unit VIII (Tractor).

VIII. References:

A. Hazardous Occupations Work in Agriculture for 4-H, Pg. 43-45.

B. Purdue Leaflet S-56.

2. Indiana requires that any vehicle traveling under 25 mph on any public highway, at a time or under circumstances specified by law for the use of lighted lamps on vehicles, there shall be displayed on such vehicles, in addition to the Slow Moving Vehicle emblem, a red or amber flashing lamp be mounted at a height as low as practicable but no more than eight feet from the ground. The flashing light must be visible for a distance of not less than 500 feet to the rear. A double faced lamp may be used, displaying amber light to the front and red or amber to the rear. This light should be used at any time the tractor is on the highway but the law only requires it when visibility is poor.

3. You are also required to have two white lights on the front of the tractor and a red tail light on the rear, at times specified in Item 2 above. They must be visible for at least 500 feet.

4. Any other safety warning device used will be helpful. Other devices are reflective tape, reflectors, red flags or additional lights.

B. What is a suitable speed for a farm tractor?

1. Farm tractors were not designed for use on public highways.

2. As speed doubles your chances for upset are four times as great.

3. It is difficult for a tractor to stop quickly especially if it is pulling a load.

4. Tractors should not travel on public highways unless there is not another alternative.

5. Tractors travel too slow for safe automobile traffic. However, tractors can travel too fast for the safety of the tractor and its operator.

6. Many items should be considered when deciding your tractor speed. They are: the condition of the road, the tractor, the traffic and the weather, also the kind of a load being pulled.

7. A rear-view mirror is a valuable safety device due to the fact that loads often obstruct the view and it is difficult for a tractor operator to hear other traffic.

5. Be sure equipment is properly hitched. (Discussed in detail in Unit IV.)

6. Check the equipment for safety. (e.g. shielding, lubrication, etc.)

B. What should one check on the instrument panel?

1. The instrument panel is there for your convience, use it.

2. Be familiar with the location and meaning of the gauges, indicators, etc. on your tractor. Keep them working properly at all times.

3. Look at them frequently to see if all systems are operating properly.

C. What should one know about gear selection, engine speed and load?

1. The experienced tractor operator knows that for economy and safety one must find the proper combination, ground speed and engine speed for equipment to run at its option level. Check the equipment manual to find this information.

2. Be familiar with the gear selection pattern for your tractor.

3. Never operate at an unsafe speed. Doubling speed increases your chances of side tipping four times. Consider the effect of speed under various field and load conditions. Field examples: Heavily loaded wagon going down hill, difficult to stop, possibility of jack-knife, etc. Rough ground, sloping ground, narrow wheels, sharp turns, high center of gravity all contribute to side tipping and they are much more hazardous at high speeds than at low speeds.

D. Why is it dangerous to overload your tractor?

1. Never overload your tractor. This is a very dangerous practice.

2. The tractor can tip backward.

3. The tractor can overheat thus causing serious damage to the engine.

4. Overloading is very hard on tires, wheels, clutches, bearings, etc.

E. What should one remember while operating on slopes?

1. Never attempt pulling a heavy load up a steep slope.

2. Always keep your tractor in gear while going down a steep slope.

3. Excessive slippage can damage tires very quickly. If you have slippage, adjustments must be made to correct the situation.

4. Slippage wastes power and can cause the tractor to flip or spin if a slipping tire suddenly catches.

5. Slippage can be decreased by adding weights to the rear of the tractor or some tractors have advice that uses the hydraulic system to decrease slippage.

K. What about dismounting?

1. Never dismount from your tractor before it stops.

2. Before dismounting shut off the tractor, place it in a low gear and lock the brakes, or place all power (PTO and tires, etc.) in neutral, lock the brakes, then dismount.

VII. Evaluation:

A. Does the student know how to operate a tractor properly in field conditions?

B. See questions on Unit VII (Tractor).

VIII. References:

A. Purdue Memo S-56

B. Hazardous Occupations in Agriculture for 4-H Members, Pg. 37

FARM MACHINERY SAFETY
...Tractor

I. Teaching Unit VIII . . . Operating Under Highway Conditions

II. Suggestions for Teaching:

A. Make a collection of data on tractor highway accidents.

B. Have a SMV emblem, a flashing light and other safety warning equipment on hand.

C. Show pictures of tractor highway accidents - see the State Police for pictures.

III. Objective:

To teach the student how to safely operate a tractor under highway conditions.

IV. Motivation:

A. About 1/3 of all fatal Indiana tractor accidents happen on highways.

B. Tell about some highway accidents. Point out that the tractor operator has little chance of surviving a serious accident.

C. Display pictures of tractor highway accidents.

D. Discuss the courteous highway usage.

V. Central Problem:

What is the safest way to operate a farm tractor on the highway?

VI. Sub-Problems:

A. What safety warning devices should one use while operating a farm tractor on a public highway?

1. Indiana state law requires that any vehicle which ordinarily travels under 25 mph must display a SMV emblem while on a public highway. The emblem should be displayed 3 to 5 feet above the ground and the point should be up.

3. Be sure that the hose is in good condition.

4. Use only hoses recommended for hydraulic pressure.

5. Be sure coupler is securely locked into position before attempting to operate hydraulic system.

6. Never allow dirt to get into the hydraulic system.

7. Never allow hoses to drag the ground or rub against machinery parts.

8. Check the oil level of the hydraulic system before using.

9. Use only oil recommended for hydraulic systems.

I. What should one remember about belt driven equipment?

1. Always ground the tractor when using belt driven equipment.

   a) Place one end of a chain over the drawbar and allow the other end to touch the ground.

   b) Static electricity can give you a bad shock or a spark could start a fire if the tractor is not grounded.

2. Drive a pole into the ground in a position so that the belt cannot rub against the front tire.

3. Use a pulley that is as wide as the belt.

4. Never attempt to operate belt above rated speed.

5. Never get near a moving power belt.

   a) The belt speed is almost 40 mph and is nearly as dangerous as a PTO.

6. Align the tractor pulley and the equipment pulley so that the belt will not come off.

J. What about proper clothing?

1. Too loose.

2. Torn or raged.

3. See Unit II, Part F, for more detailed information.

3. Decrease your speed while operating on slopes. One small hole or rut can cause an upset on a slope.

4. The use of protective frame and seat belts will help protect the operator in case of an upset on a slope.

5. Keep your brakes in equal adjustment and avoid sudden movement on slopes.

6. If you must go up a steep slope, back up.

F. How should one attempt to get out of a mud hole or ditch?

1. Always back out of mud holes and ditches. Never attempt to pull out forward or your tractor may tip backwards.

2. If you cannot back out then get help, and have someone pull you out and be sure they hitch properly.

3. Never chain a post to the rear wheels to try to get out of the mud. The tractor will either tip back or the post may fly around and hit you.

G. What hazards do riders create?

1. An extra rider has an excellent chance of falling off the tractor. A warning to "hold tight" is practically useless.

2. Never allow anyone else to ride on the tractor unless there is a seat inside a protective frame and a seat belt is used.

3. An extra rider may block your vision and distract you from your work.

H. What should one remember about making short turns?

1. If you must make a short turn, decrease your speed and proceed with caution.

2. Use your wheel brake gradually; don't depress the brake quickly even at slow speeds.

I. Why should one make observations of tires and tire slippage?

1. Inspect your tires regularly. A blow-out can cause a serious accident.

2. To check for slippage, make a line on the tractor tire with a piece of chalk, mark a starting point and move the tractor forward so that the tires make ten revolutions without a load. Measure the distance the tractor traveled. Now go to the field, and mark off the same distance. With the equipment or load attached, have someone count the number of revolutions the tire makes in the distance you have marked off. If the number of revolutions is greater than ten you have some slippage.

NATIONAL BUREAU OF STA

N TEST CHART

NDARDS-1963-A

5. It is important from a safety standpoint to have both brake pedals (A - adjusted for different pressures) (B - adjusted so pressure is applied evenly when the pedals are locked together). _____

6. The main pupose of brakes on a tractor is (A - to help make short turns in the field) (B - to make emergency stops) (C - parking the tractor) (D - all of the above). _____

UNIT VI

1. The proper horizontal distance between the end of the PTO shaft and the hitch point on the drawbar for operating the PTO at 1,000 RPM is (A - 14 inches) (B - 16 inches) (C - 10 inches) (D - 8 inches). _____

2. The ideal way to attach an implement is to have its center of pull fall (A - directly behind) (B - slightly to the right of) (C - slightly to the left of) (D - any of the above) the center of the tractor. _____

3. Raising the drawbar height (A - increases) (B - decreases) (C - has no effect on) the chance of a backward upset. _____

4. When getting ready to operate power-driven equipment, the first step is to (A - start it up and see if it is still runs) (B - be sure all of the shields and guards are in place) (C - check the speed of the PTO). _____

5. It's safe to hitch to your tractor (A - anywhere on the back end) (B - to the tractor hitch only). _____

6. Before hooking up implements to tractor it is advisable to (A - shut off tractor power) (B - leave tractor motor running). _____

7. It is (A - permitted) (B - not permitted) to operate a tractor in a closed building. _____

8. The spline for a 540 rpm PTO shaft (A - is) (B - is not) the same as the spline for a 1,000 rpm shaft. _____

9. Single-acting hydraulic cylinders (A - exert force in one direction only) (B - exert force in both directions). _____

10. Auxiliary power shafts all run at (A - 540 rmp) (B - 1,000 rpm) (C - no certain speed). _____

11. When an implement is operated with the PTO shaft in use, the drawbar should be in the (A - close) (B - extended) position. _____

12. Shortening the top link of a three-point hitch will make a plow run (A - deeper) (B - shallower). _____

13. It (A - is) (B - is not) always safe to use regular crankcase oil in the hydraulic system. _____

14. Some power line shielding is put on equipment only to meet legal requirements, but it is not really needed. T F

15. Hitching a machine to a tractor at a point lower than normal may turn the tractor over backwards on a steep slope. T F

UNIT VII

1. Tractor tire slippage can be reduced by: (A - increasing the air pressure) (B - increasing the engine speed) (C - adding weights to the rear wheels). _____

2. When going down hill tractor should be (A - placed in high gear) (B - placed in low gear) (C - neutral) (D - middle gear). _____

3. When working on slopes, near ditches or on rough, uneven ground the tractor should be operated (A - at the same speed as on level ground) (B - at faster speed than on level ground) (C - at slower speed than when working on level ground) (D - any of the above). _____

4. Extra riders are (A - always) (B - never) permitted on a tractor. _____

5. When driving a tractor downhill make certain the clutch is always (A - engaged) (B - disengaged). _____

6. When pulling a heavy load up a slope, keep the hitch (A - as low as possible) (B - as high as possible). _____

7. When climbing a very steep grade, tractor should be (A - driven as fast as possible) (B - backed up the grade). _____

8. When working hilly or rough ground, wheels on the tractor should be set (A - as wide as possible) (B - as narrow as possible). _____

9. When tractor is mired in muddy ground and you are unable to back out you should (A - chain blocks to drive wheels) (B - get someone to pull you out). _____

10. It is better to (A - back out) (B - drive out) of a ditch when the rear wheels start to spin. _____

11. Riders are not allowed on tractors but are alright on self-propelled machines such as combines. T F

UNIT VIII

1. When speed is doubled, the chance of an upset is (A - doubled) (B - three times as great) (C - four times as great) (D - the same). _____

2. If it is necessary to tow a tractor a short distance along the highway it should be towed at (A - a very slow speed) (B - ordinary tractor operating speed) (C - high speed in order to get it off the road as quickly as possible) (D - any of the above are satisfactory). _____

3. When operating a tractor on a highway, the tractor should be provided only with (A - lights and SMV emblem) (B - warning flags) (C - reflectors, lights, warning flags and SMV emblem) (D - equipment required by state law). _____

4. When operating a tractor on a highway, the tractor should be driven in (A - normal traffic lane) (B - road shoulder) (C - either of the above). _____

5. It is (A - more) (B - less) dangerous to move farm machinery on the highway than to use it on the farm. _____

6. The stopping distance for a car going 60 miles per hour, including reaction time and braking distance, is approximately (A - 100 feet) (B - 280 feet) (C - 366 feet) for a wet pavement. _____

7. It is safer to (A - pull halfway off the road) (B - get completely off the road) if someone tries to pass you on a two-lane highway. _____

8. In a collision between a tractor and a car the driver of the (A - car) (B - tractor) is more likely to become a fatality. _____

9. Safe operation of a tractor on a highway begins with (A - courtesy) (B - assuming that others will look out for your safety). _____

10. Speed is a major factor in tractor accidents. T F

UNIT IX

SAME AS UNIT VI.

e) Never get under a raised loader unless it is securely blocked or chained up.

f) Do not use a loader to lift a person or allow anyone to ride in it.

g) Position the loader so that it does not block your vision.

h) Weights should be added to the rear of a tractor before using a loader. Wheel weights give greater stability than one heavy weight added to the draw bar.

i) Become familiar with the controls and movements before attempting to use a loader or fork lift.

In summary keep wheels wide (front and rear), speed low, use extreme caution if necessary to operate on unlevel ground, keep sufficient weight on rear of the tractor.

The weight distribution problem is often overlooked; however, if the load on the front end takes most of the weight off the rear wheels, tractors tip sideways very easily.

VI. Evaluation:

Does the student know how to operate a loader or fork lift safely?

VII. Reference:

References are scattered and not very specific; therefore, they are not listed.

FARM MACHINERY SAFETY
...Tractor

I. Teaching Unit X . . . Refueling

II. Teaching Suggestions:

A. Use demonstration #8, Pg. 31 (4-H Leaders Manual).

Place a partly full safety gas can half way between a slide projector and a viewing screen. Turn the projector on. Now open the lid on the gas can. You can see a shadow of the vapors flowing out and down.

B. Collect data on refueling accidents.

C. Obtain film, "Farm Petro Safety."

D. Place a small piece of cotton soaked with gasoline in a metal trough. Tilt the trough in a 45 degree angle. Put a lighted candle at the top end them put it at the bottom end. The cotton will catch fire while the candle is at the bottom.

III. Objective:

To teach the student how to refuel a farm tractor safely.

IV. Motivation:

A. Show film, "Farm Petroleum Safety."

B. Give Demonstration II A.

C. One gallon of gasoline has the explosive power of 87 pounds of dynamite.

D. Give demonstration II D.

V. Central Problem:

What is the proper procedure in refueling a farm tractor?

VI. Sub-Problem:

A. How should one refuel a gasoline tractor?

1. Never refuel around fire or sparks. One gallon of gasoline has the same explosive forces as 87 pounds of dynamite. However, gasoline will not burn in the liquid state. Gasoline will vaporize at -45°F. The gasoline state will explode quite readily. Gasoline vapors are heavier than air, therefore, these vapors will move down around the tractor engine and tend to stay near the ground for a period of time.

Preface

Tremendous innovations and revisions are taking place in American elementary and secondary education today. Whether these changes turn out to be minor or substantial, temporary or permanent, bad or good, depends most of all on the quality and nature of leadership at the local school level.

This Handbook, originally conceived as a set of guidelines for the use of member school districts of the Curriculum Development Council for Southern New Jersey, has been developed for a more universal use. It is a guide for administrators, teachers, and consultants engaged in curriculum development at the local level in any school system, particularly one which relies on some outside consultant help.

The Curriculum Development Council is a non-profit educational organization of public school districts associated with Glassboro State College for the purposes of study and action in selected curriculum areas, and for the exchange of ideas and experiences.

The Council's method of operation is to engage experienced consultants to work with local study committees on curriculum problems of local importance. Each committee makes plans for study and experimentation under the guidance of the consultant, conducts the experimentation, and is asked to submit an annual report on its work. The Council also conducts conferences and prepares publications for its members.

The Handbook is divided into three major sections. Chapters I and II state general principles and indicate supporting references. Chapters III through VI outline specific processes and develop the roles involved in curriculum change, as tested by members of the Curriculum Development Council in accord with the principles previously developed. Chapter VII shows how ideas about leadership and curriculum change have applied as the Council has worked with school systems.

In order that schools may get maximum use from this publication, the Curriculum Development Council authorizes administrators and teachers to use or reproduce ideas verbatim or adapt them as they see fit. However, no part of this Handbook may be reproduced for commercial purposes, nor may quotations be used that appear in this material but are credited to another source.

HARRY T. GUMAER
Series Editor

QUESTIONS FOR FARM SAFETY

UNIT I

1. It takes half a second for a tractor accident to happen. In any emergency it may take you (A - 1/10 second) (B - one second or more) (C - 1/2 second) (D - 3/4 second) to make the proper reaction to avoid the accident. _____

2. Being a safe operator is mostly a matter of (A - pure chance) (B - thinking ahead and avoiding accident situations) (C - skill and luck) (D - none of these). _____

3. It has been estimated that (A - 50) (B - 30) (C - over 80) (D - 10) percent of accidents are caused by operator error. _____

4. Safe operation of farm machinery is (A - impossible) (B - a matter of pure chance) (C - learning and practicing safe procedures at all times). _____

5. A modern tractor is about (A - 5) (B - 50) (C - 500)(D - 5,000) times more powerful than the average man. _____

6. Diseases kill (A - more) (B - fewer) farm children than accidents. _____

7. A good way to prevent a tractor accident is (A - take your chances) (B - make sure your tractor is safe at all times). _____

8. Records show that accidents are caused by (A - working when tired) (B - trying to hurry) (C - not using what you have learned about being a safe tractor operator) (D - all of the above). _____

9. Many accidents result from a momentary lack of attention. T F

10. It has been estimated that 10% of the accidents with farm machinery were unavoidable. T F

11. The simplest and easiest way to avoid accidents is to think about accident situations. T F

12. Your natural reaction in an accident situation is either to do nothing at all, or to make the wrong move. T F

UNIT II

1. The liquid in a battery is a solution of water and (A - hydrochloric acid) (B - sulfuric acid) (C - nitric acid) (D - acetic acid). _____

2. It is possible to ruin an engine in (A - one hour) (B - one day) (C - one week) (D - one month) by operating it with the air cleaner out of order. _____

1. Never refuel around fire or sparks. One gallon of gasoline has the same explosive force as 87 pounds of dynamite. However, gasoline will not burn in the liquid state. Gasoline will vaporize at -45°F. The gaseous state will explode quite readily. Gasoline vapors are heavier than air, therefore, these vapors will move down around the tractor engine and tend to stay near the ground for a period of time.
2. Never refuel a hot or a running engine.
3. If you spill gasoline on the tractor, allow the fuel to vaporize completely and blow away before you attempt to start the engine. Remember only one spark is required to create an explosion.
4. Keep the container or hose nozzle against the funnel or fuel tank to prevent static electricity from igniting the gasoline vapors.
5. Never over fill the fuel tank. While you are driving the fuel can splash out onto the hot engine. Also never operate a tractor without a nonsurge gasoline filler cap.
6. If you are refueling from portable gas cans, always use a funnel to prevent spilling and use only a safety gasoline can (one with a self closing cap.)
7. Never smoke around gasoline.

B. How should one refuel a diesel tractor?

1. Diesel fuel does not vaporize as quickly as gasoline but it is also dangerous to refuel around spark or fire.
2. Since diesel fuel does not vaporize quickly, if spilled it can cause a fall. It vaporizes at about 100°F.

3. Never refuel a hot or a running engine.

4. If you spill fuel on the tractor, allow the fuel to vaporize completely and blow away before you attempt to start the engine. Remember only one spark is required to create an explosion.

5. Keep the container or hose nozzle against the funnel or fuel tank to prevent static electricity from igniting the fuel vapors.

6. Never over fill the fuel tank. While you are driving the fuel can splash out onto the hot engine. Also never operate a tractor without a nonsurge gasoline filler cap.

7. If you are refueling from portable gas cans, always use a funnel to prevent spilling and use only a safety gasoline can (one with a self closing cap).

8. Never smoke around gasoline.

9. Diesel fuel does not vaporize as quickly as gasoline but it is also dangerous to refuel around spark or fire.

10. Since diesel fuel does not vaporize quickly, if spilled it can cause a fall. It vaporizes at about 100°F.
